Abstract

This is the first of a series of two technical papers devoted to the analysis of holonomy invariants in strict higher gauge theory with end applications in higher Chern–Simons theory. For a flat 2–connection, we define the 2-holonomy of surface knots of arbitrary genus and determine its covariance properties under 1–gauge transformation and change of base data.

Keywords: quantum field theory in curved space–time; geometry, differential geometry and topology. PACS: 04.62.+v 02.40.-k

1 Introduction

One of the basic problems in 3–dimensional topology is the classification of topologically distinct knots [1, 2]. Knots which can be smoothly deformed into one other are topologically indistinguishable though they may appear completely unlike upon superficial inspection. Knot invariants take the same value for all topologically identical knots. Computing knot invariants, therefore, allows one to ascertain whether two given knots are topologically distinct or not. If they have different knot invariants, they are.

Ordinary Chern–Simons theory allows in principle the computation of knot invariants using quantum field theory [3,4]. In this respect, it has been extraordinarily successful. A variety of methods have been devised, perturbative and non perturbative as well, including large level asymptotics, canonical quantization and reduction to random matrix integrals [5].

In topology, the problem of the classification of knots in 3 dimensions has higher dimensional analogs. What is a higher knot? As ordinary knots are embeddings of the circle S^1 into the 3–sphere S^3, say, n–dimensional knots may be defined as embeddings of the n–sphere S^n into the $n+2$–sphere S^{n+2}. Actually this is only one of the possible generalization of the notion of knot. S^1 is not only the lowest dimensional non trivial sphere, but it is also the only compact 1–dimensional manifold without boundary. Thus, one may also define n–dimensional knots as embeddings of a compact boundaryless n–fold X into S^{n+1}. For $X = S^n$, the former more restrictive definition is recovered.

The problem is already quite involved for 2–dimensional knots [6, 7]. We distinguish 2–knots, defined as embeddings of S^2 into S^4, and surface knots, defined as embeddings of a compact surface S with no boundary into S^4. Surface knots can be classified according to the genus ℓ_S of S. 2–knots are just genus 0 surface knots. In this paper, we shall concentrate on surface knots.

Given the success of ordinary Chern–Simons theory as a quantum field theoretic framework for the computation of ordinary knot invariants, it is conceivable that higher dimensional versions of Chern–Simons theory may compute higher knot invariants. In particular, a 4–dimensional Chern–Simons theory would be required to deal with surface knot invariants. However, this already poses a problem. The higher dimensional analogs of plane Chern–Simons theory exist only in odd dimensional spaces and are not guaranteed to do the job. In fact, alternative approaches to the problem relying on BF theory instead have been developed [8]. There is by now a growing evidence that the incarnation of Chern–Simons theory appropriate for higher knot theory may belong to the realm of higher gauge theory [9, 10]. See refs. [11, 12] for a readable introduction to the subject and refs. [13, 14] for a more comprehensive in depth treatment.

In refs. [15, 16], a higher gauge theoretic 4–dimensional Chern–Simons model whose symmetry is encoded in a balanced cyclic 2–term L_∞ algebra has been constructed. The model resembles in many ways the usual Chern–Simons model, but at the moment it is not clear whether it exists as a quantum field theory, though there are some indications in this direction. It is a promising candidate deserving further investigation.

In ordinary Chern–Simons theory, the field theoretic computation of knot invariants involves the evaluation of traces of Wilson loops of the gauge field, mathematically holonomies of the gauge connection, along knots in representations of the gauge group. In the present endeavour, we consider the corresponding issue for surface knots in a strict higher gauge theory. The problem has two parts: (a) the definition of surface holonomies and the study of the way they depend on the choice of gauge and base data; (b) the definition of the appropriate notion of trace for the gauge crossed module such to give surface knot invariants upon application to surface holonomies. The first part is treated in the present work, the second one in a companion paper [17].

1.1 Scope and plan of the paper

The goal of the present paper is working out a rigorous definition of surface knot holonomy in strict higher gauge theory that is suitable for a gauge theoretic computation of surface knot invariants. In this subsection, we outline our results with no pretence of mathematical rigour.

Early investigations on surface holonomy include refs. [8,18]. Higher parallel transport was studied in depth in refs. [19–28]. The problem of defining surface holonomy was tackled already in refs. [24,25] and, more recently, it has been analyzed in refs. [29–32] from a variety of points of view.

To make the reader appreciate the import of our results, it is useful to review first briefly knot holonomy in ordinary gauge theory. Consider a gauge theory with gauge group G on a 3–fold M with a trivial principal G–bundle as gauge background, the situation normally envisaged in Chern–Simons theory. A connection, physically a gauge field, is then a $\mathfrak{g}$–valued 1–form θ.

Knots are closed embedded curves in M. As it turns out, knot holonomy is defined for based knots, that is knots which begin and end at some point of M. For this reason, at an initial level of analysis, it is natural to assume that M is pointed by a distinguished point p_M and restrict the analysis to knots based at p_M.

Given a *flat* connection θ, with each knot ξ in M there is associated its holonomy $F_\theta(\xi) \in G$ by a classical construction. The flatness of θ ensures that $F_\theta(\xi)$ is invariant under smooth deformations of ξ which leave p_M fixed.

A gauge transformation is a G–valued map g. Gauge transformations act on connections. Under a gauge transformation g, the flat connection θ turns into another one ${}^g\theta$. Correspondingly, the holonomy of a knot ξ transforms as

$$F_{{}^g\theta}(\xi) = g(p_M)F_\theta(\xi)g(p_M)^{-1}. \tag{1.1.1}$$

Of course, we do not want to commit ourselves with a final choice of pointing of M. Thus, at the next level of analysis, it is necessary to find out how holonomy depends on the latter. Suppose that p_{M0}, p_{M1} are two distinct pointings of M such that there exists a curve γ_1 connecting p_{M0} to p_{M1}. If ξ_0, ξ_1 are two knots based at p_{M0}, p_{M1}, respectively, which can be smoothly deformed into one another, then the holonomies $F_\theta(\xi_0)$, $F_\theta(\xi_1)$ satisfy

$$F_\theta(\xi_1) = F_\theta(\gamma_1) F_\theta(\xi_0) F_\theta(\gamma_1)^{-1}, \tag{1.1.2}$$

where $F_\theta(\gamma_1) \in G$ is the customary parallel transport along γ_1.

In this paper, we propose a natural and physically intuitive extension of the above simple holonomic framework to strict higher gauge theory capable of computing holonomies of surface knots.

Consider a strict higher gauge theory with gauge crossed module (G, H) on a 4–fold M with a trivial principal (G, H)–2–bundle as gauge background, the situation presumably relevant in the appropriate higher gauge theoretic version of 4–dimensional Chern–Simons theory. A 2–connection is now a doublet of a $\mathfrak{g}$–valued 1–form θ and a $\mathfrak{h}$–valued 2–form $\varUpsilon$ satisfying a certain compatibility requirement known as zero fake curvature condition.

Analogously to common knots, surface knots are closed embedded surfaces in M. Surface knot holonomy is defined for based surface knots of M, that is knots whose independent non contractible loops, called characteristic knots, are specified closed curves. For this reason, much as in the ordinary case, at an initial level of analysis, it is natural to assume that M is marked by a distinguished point p_M and a special set of closed curves ζ_{Mi} based at p_M and restrict to surface knots whose characteristic knots equal the ζ_{Mi}. There are conditions on the number and type of the ζ_{Mi} which have to be met. A non trivial feature of surface knot theory is its requirement of a reference "trivial" surface knot. A comprehensive treatment of surface knot theory is provided in subsects. 2.1–2.3.

2–Connection doublets can be flat as ordinary connections. In subsect. 3.1, we show that, given a *flat* 2–connection doublet $(\theta, \varUpsilon)$, with each surface knot $\varXi$ in M of genus $\ell_{\varXi}$ there are associated its surface holonomy $F_{\theta,\varUpsilon}(\varXi) \in H$ and the holonomies $F_\theta(\zeta_{Mi}) \in G$ of its $2\ell_{\varXi}$ characteristic knots ζ_{Mi}. The flatness of $(\theta, \varUpsilon)$ ensures that $F_{\theta,\varUpsilon}(\varXi)$ and the $F_\theta(\zeta_{Mi})$ are invariant under smooth deformations of $\varXi_i$ which leave p_M and the ζ_{Mi} fixed.

The surface holonomy of a surface knot $\varXi$ belongs to the kernel of the target morphism t of the crossed module (G, H)

$$t(F_{\theta,\varUpsilon}(\varXi)) = 1_H. \tag{1.1.3}$$

Non trivial surface holonomy is thus possible only if the kernel of t is non trivial.

A 1–gauge transformation doublet consists of G–valued map g and an $\mathfrak{h}$–valued 1–form J. 1–gauge transformation doublets act on 2–connection doublets. Under a 1–gauge transformation (g, J), the flat 2–connection doublet $(\theta, \varUpsilon)$ turns into another one $({}^{g,J}\theta, {}^{g,J}\varUpsilon)$. In subsect. 3.2, we show that the surface holonomy of a surface knot $\varXi$ and the holonomies of its characteristic knots ζ_{Mi} correspondingly transform as

$$F_{{}^{g,J}\theta,{}^{g,J}\varUpsilon}(\varXi) = m(g(p_M))(F_{\theta,\varUpsilon}(\varXi)), \tag{1.1.4}$$

where m denotes the G–action morphism of the crossed module (G, H), and

$$F_{{}^{g,J}\theta}(\zeta_{Mi}) = g(p_M)t(G_{g,J;\theta}(\zeta_{Mi}))F_\theta(\zeta_{Mi})g(p_M)^{-1}, \tag{1.1.5}$$

where $G_{g,J;\theta}(\zeta_{Mi}) \in H$ is an appropriately defined gauge holonomy of ζ_{Mi}.

In subsect. 3.3, moving to the next level of analysis, we find out how surface holonomy depends on the choice of the marking of M. Suppose that p_{M0}, ζ_{M0i}, p_{M1}, ζ_{M1i} are two markings that can be smoothly deformed into one another, so that there exist a curve γ_1 joining p_{M0} to p_{M1} and, for each i, a surface $\varSigma_i$ stretching from ζ_{M0i} to ζ_{M1i}. If $\varXi_0$, $\varXi_1$ are two surface knots based at the ζ_{M0i},

ζ_{M1i}, respectively, related by the same deformation, then the surface holonomies $F_{\theta,\Upsilon}(\Xi_0)$, $F_{\theta,\Upsilon}(\Xi_1)$ are related as

$$F_{\theta,\Upsilon}(\Xi_1) = m(F_\theta(\gamma_1))(F_{\theta,\Upsilon}(\Xi_0)), \tag{1.1.6}$$

whilst the line holonomies $F_\theta(\zeta_{M0i})$, $F_\theta(\zeta_{M1i})$ accord as

$$F_\theta(\zeta_{M1i}) = F_\theta(\gamma_1)t(F_{\theta,\Upsilon}(\Sigma_i))F_\theta(\zeta_{M0i})F_\theta(\gamma_1)^{-1}, \tag{1.1.7}$$

where $F_\theta(\gamma_1) \in G$ is the line parallel transport along γ_1 and, for each i, $F_{\theta,\Upsilon}(\Sigma_i) \in H$ is the surface parallel transport along Σ_i, all defined according to an appropriate higher gauge theoretic prescription.

1.2 Outlook

The results we have succinctly expounded above suggest a possible avenue for the definition of surface knot invariants. In ordinary gauge theory, relations (1.1.1) and (1.1.2) indicate that any construction of knot invariants out of knot holonomies that is gauge and pointing choice independent can be achieved only by conjugation invariant mappings $\chi : G \to T$, where T is some set. An obvious choice of χ are the characters of the representations R of G, tr_R. In strict higher gauge theory, (1.1.1) and (1.1.2) are replaced by relations (1.1.5), (1.1.4) and (1.1.7), (1.1.6), respectively. These show that, in order to obtain gauge and marking choice independent surface knot invariants out of surface knot holonomies, one needs an extension of the notion of conjugation invariant mappings from groups to crossed modules. This problem will be analyzed in the companion paper [17] using the theory of higher quandles.

2 Surface knot theory

In this section, the theory of knots is reviewed and that of surface knots is thoroughly expounded. With the term "knot theory", we do not mean the topological theory of knots as detailed for instance in refs. [1,2] and, in the higher case, in refs. [6,7]. What we are to delineate is a formal framework capable of associating with any knot a curve with sitting instants and, by extension, with any surface knot a surface with sitting instants with natural properties [33]. The definition and analysis of holonomy presented in the subsequent section, in fact, work only for curves and surfaces with sitting instants. Only very basic notions of the topological theory such as those of smooth embedding, smooth homotopy and ambient isotopy will be invoked in the following inquiry.

Because of the nature of our approach we have just recalled, it is not required anywhere that knots or surface knots have codimension 2 in the ambient manifold. Therefore, we only assume that the dimension of the latter is sufficiently large to allow for embeddings of the relevant types. The interesting applications, of course, belong to the codimension 2 case.

2.1 Curves, surfaces and homotopy

In this subsection, we survey the basic notions of curves and surfaces and of thin homotopy and homotopy thereof expressing them in a way that is suited for higher parallel transport and holonomy theory. We do not stress however the categorical aspects of the subject, though they are admittedly important. This material is not original and is presented mainly to make this paper self–contained. For this reason, we give no proof of the basic results.

As an introduction to the topic, we review first the familiar definitions of curves and thin homotopy and homotopy thereof used in the formulation of parallel transport of ordinary gauge theory.

Definition 2.1.1 *Let* p_0, p_1 *be points of* M*. A curve* $\gamma : p_0 \to p_1$ *of* M *with sitting instants is a mapping* $\gamma \in \mathrm{Map}(\mathbb{R}, M)$ *satisfying*

$$\gamma(x) = p_0 \qquad \text{for } x < \epsilon, \tag{2.1.1a}$$

$$\gamma(x) = p_1 \qquad \text{for } x > 1 - \epsilon \tag{2.1.1b}$$

for some $\epsilon > 0$ *with* $\epsilon < 1/2$ *depending on* γ*. The curve* γ *is called closed if* $p_0 = p_1$*. In such a case,* γ *is said based at* p_0*.*

All curves considered in this paper will be assumed to have sitting instants unless otherwise stated.

Definition 2.1.2 *Let* p *be a point of* M*. The unit curve* $\iota_p : p \to p$ *of* p *is the curve defined by*

$$\iota_p(x) = p. \tag{2.1.2}$$

Let p_0, p_1 *be points and* $\gamma : p_0 \to p_1$ *be a curve of* M*. The inverse curve of* γ *is the curve* $\gamma^{-1\circ} : p_1 \to p_0$ *given by*

$$\gamma^{-1\circ}(x) = \gamma(1 - x). \tag{2.1.3}$$

Let p_0, p_1, p_2 *be points and* $\gamma_1 : p_0 \to p_1$*,* $\gamma_2 : p_1 \to p_2$ *be curves of* M*. The composition of* γ_1*,* γ_2 *is the curve* $\gamma_2 \circ \gamma_1 : p_0 \to p_2$ *defined piecewise by*

$$\gamma_2 \circ \gamma_1(x) = \gamma_1(2x) \qquad \text{for } x \le 1/2, \tag{2.1.4a}$$

$$\gamma_2 \circ \gamma_1(x) = \gamma_2(2x - 1) \qquad \text{for } x \ge 1/2. \tag{2.1.4b}$$

In gauge theory, parallel transport along curves, especially in the form of holonomy along closed curves, enjoys properties of homotopy invariance which make it one of the basic elements of the gauge theoretic construction of knot invariants. Homotopy plays therefore a fundamental role. It comes in two forms which are defined next.

Definition 2.1.3 *Let p_0, p_1 be points and $\gamma_0, \gamma_1 : p_0 \to p_1$ be curves. A thin homotopy $h : \gamma_0 \Rightarrow \gamma_1$ is a mapping $h \in \mathrm{Map}(\mathbb{R}^2, M)$ such that*

$$h(x, y) = p_0 \qquad \text{for } x < \epsilon, \tag{2.1.5a}$$

$$h(x, y) = p_1 \qquad \text{for } x > 1 - \epsilon, \tag{2.1.5b}$$

$$h(x, y) = \gamma_0(x) \qquad \text{for } y < \epsilon, \tag{2.1.5c}$$

$$h(x, y) = \gamma_1(x) \qquad \text{for } y > 1 - \epsilon \tag{2.1.5d}$$

for some $\epsilon > 0$ with $\epsilon < 1/2$ and that

$$\mathrm{rank}(dh(x, y)) \leq 1. \tag{2.1.6}$$

γ_0, γ_1 are called thin homotopy equivalent if there is thin homotopy $h : \gamma_0 \Rightarrow \gamma_1$. If condition (2.1.6) *is dropped, then $h : \gamma_0 \Rightarrow \gamma_1$ is called a homotopy and γ_0, γ_1 are called homotopy equivalent.*

Let N, M be manifolds and let $f : N \to M$ be a map. We can left compose by f curves γ and (thin) homotopies of curves h in N regarded as maps with target N and obtain curves $f \circ \gamma$ and (thin) homotopies of curves $f \circ h$ in M as established by the following proposition.

Proposition 2.1.1 *Let p_0, p_1 be points and $\gamma : p_0 \to p_1$ be a curve of N. Then, $f \circ \gamma : f(p_0) \to f(p_1)$ is a curve of M, called the push–forward of γ by f.*
Let p_0, p_1 be points and $\gamma_0, \gamma_1 : p_0 \to p_1$ be curves of N. If $h : \gamma_0 \Rightarrow \gamma_1$ is a (thin) homotopy in N, then $f \circ h : f \circ \gamma_0 \Rightarrow f \circ \gamma_1$ is a (thin) homotopy in M, called the push–forward of h by f.

Let $\Pi_1 M$ be the set of all curves of a manifold M. Def. 2.1.2 endows $(M, \Pi_1 M)$ with a pregroupoid structure, that is a set of operations of the kind that would be required for $(M, \Pi_1 M)$ to be a groupoid. As is well–known, however, $(M, \Pi_1 M)$ is not one, as invertibility and associativity fail to hold.

It is readily verified that both thin homotopy and homotopy are equivalence relations on $\Pi_1 M$ compatible with the pregroupoid structure of $(M, \Pi_1 M)$. Upon replacing $\Pi_1 M$ with the sets $P_1 M$ and $P^0{}_1 M$ of all thin homotopy and homotopy classes of curves of M, respectively, and equipping $(M, P_1 M)$ and $(M, P^0{}_1 M)$ with the pregroupoid structure induced by that of $(M, \Pi_1 M)$, one obtains two genuine groupoids $(M, P_1 M)$ and $(M, P^0{}_1 M)$, called the path and the fundamental groupoids of M, respectively. The content of these groupoids has the intuitive diagrammatic representation

$$\begin{tikzcd} p_1 & p_0 \arrow[l, "\gamma"'] \end{tikzcd}, \tag{2.1.7}$$

where γ is understood as a (thin) homotopy class of curves. $(M, P_1 M)$, $(M, P^0{}_1 M)$ enter in a basic way in the categorical theory of parallel transport. A formulation along this lines has been developed in refs. [21–23], but lies outside the scope of this paper.

The above constructions have a higher extension. To curves connecting pairs of points, one adds surfaces stretching between pairs of curves with common endpoints. We now review the definitions of curves, surfaces and thin homotopy and homotopy thereof used in the formulation of higher parallel transport.

Definition 2.1.4 *For any two points p_0, p_1 of M, a curve $\gamma : p_0 \to p_1$ with sitting instants, in particular a closed one, is characterized as in def. 2.1.1.*
Let p_0, p_1 be points and $\gamma_0, \gamma_1 : p_0 \to p_1$ be curves of M. A surface $\varSigma : \gamma_0 \Rightarrow \gamma_1$ of M with sitting instants is a map $\varSigma \in \mathrm{Map}(\mathbb{R}^2, M)$ such that

$$\varSigma(x, y) = p_0 \qquad \textit{for } x < \epsilon, \tag{2.1.8a}$$

$$\varSigma(x, y) = p_1 \qquad \textit{for } x > 1 - \epsilon, \tag{2.1.8b}$$

$$\varSigma(x, y) = \gamma_0(x) \qquad \textit{for } y < \epsilon, \tag{2.1.8c}$$

$$\varSigma(x, y) = \gamma_1(x) \qquad \textit{for } y > 1 - \epsilon \tag{2.1.8d}$$

for some $\epsilon > 0$ *with* $\epsilon < 1/2$ *depending on* γ_0, γ_1, Σ. *The surface* Σ *is called closed if* $\gamma_0 = \gamma_1$. *In such a case,* Σ *is said to be based at* γ_0.

As with curves, all surfaces considered in this paper will be assumed to have sitting instants unless otherwise stated.

Definition 2.1.5 *For a point* p *of* M*, the unit curve* $\iota_p : p \to p$ *of* p *is defined as in* (2.1.2). *For points* p_0, p_1 *and a curve* $\gamma : p_0 \to p_1$ *of* M*, the inverse curve* $\gamma^{-1\circ} : p_1 \to p_0$ *is defined as in* (2.1.3). *For points* p_0, p_1, p_2 *and curves* $\gamma_1 : p_0 \to p_1$, $\gamma_2 : p_1 \to p_2$ *of* M*, the composed curve* $\gamma_2 \circ \gamma_1 : p_0 \to p_2$ *is defined as in* (2.1.4).

Let p_0, p_1 *be points and* $\gamma : p_0 \to p_1$ *be a curve of* M. *The unit surface* $I_\gamma : \gamma \Rightarrow \gamma$ *of* γ *is the surface given by*

$$I_\gamma(x, y) = \gamma(x). \tag{2.1.9}$$

Let p_0, p_1 *be points,* $\gamma_0, \gamma_1 : p_0 \to p_1$ *be curves and* $\Sigma : \gamma_0 \Rightarrow \gamma_1$ *be a surface of* M. *The vertical inverse of* Σ *is the surface* $\Sigma^{-1\bullet} : \gamma_1 \Rightarrow \gamma_0$

$$\Sigma^{-1\bullet}(x, y) = \Sigma(x, 1 - y). \tag{2.1.10}$$

Let p_0, p_1 *be points,* $\gamma_0, \gamma_1, \gamma_2 : p_0 \to p_1$ *be curves and* $\Sigma_1 : \gamma_0 \Rightarrow \gamma_1$, $\Sigma_2 : \gamma_1 \Rightarrow \gamma_2$ *be surfaces of* M. *The vertical composition of* Σ_1, Σ_2 *is the surface* $\Sigma_2 \bullet \Sigma_1 : \gamma_0 \Rightarrow \gamma_2$ *defined piecewise by*

$$\Sigma_2 \bullet \Sigma_1(x, y) = \Sigma_1(x, 2y) \qquad \text{for } y \leq 1/2, \tag{2.1.11a}$$

$$\Sigma_2 \bullet \Sigma_1(x, y) = \Sigma_2(x, 2y - 1) \qquad \text{for } y \geq 1/2. \tag{2.1.11b}$$

Let p_0, p_1 *be points,* $\gamma_0, \gamma_1 : p_0 \to p_1$ *be curves and* $\Sigma : \gamma_0 \Rightarrow \gamma_1$ *be a surface of* M. *The horizontal inverse of* Σ *is the surface* $\Sigma^{-1\circ} : {\gamma_0}^{-1\circ} \Rightarrow {\gamma_1}^{-1\circ}$

$$\Sigma^{-1\circ}(x, y) = \Sigma(1 - x, y). \tag{2.1.12}$$

Let p_0, p_1, p_2 be points, $\gamma_0, \gamma_1 : p_0 \to p_1$, $\gamma_2, \gamma_3 : p_1 \to p_2$ be curves and $\Sigma_1 : \gamma_0 \Rightarrow \gamma_1$, $\Sigma_2 : \gamma_2 \Rightarrow \gamma_3$ be surfaces of M. The horizontal composition of Σ_1, Σ_2 is the surface $\Sigma_2 \circ \Sigma_1 : \gamma_2 \circ \gamma_0 \Rightarrow \gamma_3 \circ \gamma_1$ given piecewise by

$$\Sigma_2 \circ \Sigma_1(x, y) = \Sigma_1(2x, y) \qquad \text{for } x \leq 1/2, \tag{2.1.13a}$$

$$\Sigma_2 \circ \Sigma_1(x, y) = \Sigma_2(2x - 1, y) \qquad \text{for } x \geq 1/2. \tag{2.1.13b}$$

In higher gauge theory, analogously to the ordinary one, higher parallel transport along curves and surfaces, in particular holonomy along closed curves and surfaces, enjoys properties of homotopy invariance which make it a candidate as one of the basic elements of the higher gauge theoretic construction of surface knot invariants, which is the main goal of the present paper. Again, therefore, homotopy plays a fundamental role. Again, it comes in two forms which are defined next.

Definition 2.1.6 *For any two points p_0, p_1 and curves $\gamma_0, \gamma_1 : p_0 \to p_1$ of M, a thin homotopy $h : \gamma_0 \Rightarrow \gamma_1$ and the thin homotopy equivalence of γ_0, γ_1 are characterized as in def. 2.1.3.*
Let p_0, p_1 be points, $\gamma_0, \gamma_1, \gamma_2, \gamma_3 : p_0 \to p_1$ be curves and $\Sigma_0 : \gamma_0 \Rightarrow \gamma_1$, $\Sigma_1 : \gamma_2 \Rightarrow \gamma_3$ be surfaces of M. A thin homotopy of $H : \Sigma_0 \Rrightarrow \Sigma_1$ is a mapping $H \in \mathrm{Map}(\mathbb{R}^3, M)$ such that

$$H(x, y, z) = p_0 \qquad \text{for } x < \epsilon, \tag{2.1.14a}$$

$$H(x, y, z) = p_1 \qquad \text{for } x > 1 - \epsilon, \tag{2.1.14b}$$

$$H(x, y, z) = H(x, 0, z) \qquad \text{for } y < \epsilon, \tag{2.1.14c}$$

$$H(x, y, z) = H(x, 1, z) \qquad \text{for } y > 1 - \epsilon, \tag{2.1.14d}$$

$$H(x, y, z) = \Sigma_0(x, y) \qquad \text{for } z < \epsilon, \tag{2.1.14e}$$

$$H(x, y, z) = \Sigma_1(x, y) \qquad \text{for } z > 1 - \epsilon \tag{2.1.14f}$$

for some $\epsilon > 0$ with $\epsilon < 1/2$ and that

$$\operatorname{rank}(dH(x,0,z)),\ \ \operatorname{rank}(dH(x,1,z)) \leq 1, \tag{2.1.15a}$$

$$\operatorname{rank}(dH(x,y,z)) \leq 2. \tag{2.1.15b}$$

Σ_0, Σ_1 are called thin homotopy equivalent if there is a thin homotopy $H : \Sigma_0 \Rrightarrow \Sigma_1$. If condition (2.1.15b) *is not imposed, then $H : \Sigma_0 \Rrightarrow \Sigma_1$ is called a homotopy and Σ_0, Σ_1 are called homotopy equivalent.*

We note that condition (2.1.15a) implies that the source curves γ_0, γ_2 of Σ_0, Σ_1 are thin homotopy equivalent, and similarly the target ones γ_1, γ_3.

Let N, M be manifolds and let $f : N \to M$ be a map. We can left compose by f curves γ, surfaces Σ, thin homotopies of curves h and (thin) homotopies of surfaces H in N regarded as maps with target N and obtain curves $f \circ \gamma$, surfaces $f \circ \Sigma$, thin homotopies of curves $f \circ h$ and (thin) homotopies of surfaces $f \circ H$ in M. This is detailed in the following proposition.

Proposition 2.1.2 *The statements of prop. 2.1.1 about curves and homotopies of curves continue to hold with the exclusion of those concerning non thin homotopies.*
Let p_0, p_1 be points, $\gamma_0, \gamma_1 : p_0 \to p_1$ be curves and $\Sigma : \gamma_0 \Rightarrow \gamma_1$ be a surface of N. Then, $f \circ \Sigma : f \circ \gamma_0 \Rightarrow f \circ \gamma_1$ is a surface of M, the push–forward of Σ by f.
Let p_0, p_1 be points, $\gamma_0, \gamma_1, \gamma_2, \gamma_3 : p_0 \to p_1$ be curves and $\Sigma_0 : \gamma_0 \Rightarrow \gamma_1$, $\Sigma_1 : \gamma_2 \Rightarrow \gamma_3$ be surfaces of N. If $H : \Sigma_0 \Rrightarrow \Sigma_1$ is a (thin) homotopy of surfaces in N, then $f \circ H : f \circ \Sigma_0 \Rrightarrow f \circ \Sigma_1$ is a (thin) homotopy in M, called the push-forward of H by f.

Let $\Pi_1 M$, $\Pi_2 M$ be the sets of all curves and surfaces of M, respectively. Def. 2.1.5 endows $(M, \Pi_1 M, \Pi_2 M)$ with a 2–pregroupoid structure, that is a set of operations of the kind that would be required for $(M, \Pi_1 M, \Pi_2 M)$ to be a groupoid. Analogously to the ordinary case, $(M, \Pi_1 M, \Pi_2 M)$ is not one however, as invertibility and associativity fail to hold both for curves and surfaces in the vertical as well as the horizontal variants.

Thin homotopy of curves and (thin) homotopy of surfaces are equivalence relations on $\Pi_1 M$, $\Pi_2 M$, respectively, compatible with the 2–pregroupoid structure of $(M, \Pi_1 M, \Pi_2 M)$. Upon replacing $\Pi_1 M$ with the set $P_1 M$ of all thin homotopy classes of curves and $\Pi_2 M$ with the sets of thin homotopy and homotopy classes of surfaces, respectively, and equipping $(M, P_1 M, P_2 M)$ and $(M, P_1 M, P^0{}_2 M)$ with the 2–pregroupoid structure induced by that of $(M, \Pi_1 M, \Pi_2 M)$, one obtains two genuine 2–groupoids $(M, P_1 M, P_2 M)$ and $(M, P_1 M, P^0{}_2 M)$, called the path and the fundamental 2–groupoid of M, respectively. The content of these 2–groupoids has the intuitive diagrammatic representation

$$\begin{tikzcd} p_1 & p_0 \arrow[l, bend right, "\gamma_0"', ""{name=U, below}] \arrow[l, bend left, "\gamma_1", ""{name=D, above}] \arrow[Rightarrow, from=U, to=D, "\Sigma"'] \end{tikzcd} \tag{2.1.16}$$

where γ_0, γ_1 are understood as thin homotopy classes of curves and Σ as a (thin) homotopy class of surfaces. In [21–23], the categorical theory of higher parallel transport based on $(M, P_1 M, P_2 M)$, $(M, P_1 M, P^0{}_2 M)$ has been worked out, but we shall not rely on it in this paper.

2.2 2–knots and their associated surfaces

In this subsection, we shall study how one can describe higher knots in a way suitable for higher gauge theory.

In what follows, the terms curves and surfaces will be always used with the meaning stated in defs. 2.1.1, 2.1.4 unless otherwise stated. Curves and surfaces understood as topological/differentiable 1– and 2–dimensional manifolds will be called topological/differentiable curves and surfaces, respectively.

Before proceeding to the study of knots, it is necessary to recall a few basic notions of differential topology.

Definition 2.2.1 *Let M, N be manifolds and let $f_0,\ f_1 : N \to M$ be maps. A homotopy h of f_0, f_1 with sitting instants is a smooth family $h_u : N \to M$, $u \in \mathbb{R}$, of maps such that*

$$h_u = f_0 \qquad \text{for } u < \epsilon, \tag{2.2.1a}$$

$$h_u = f_1 \qquad \text{for } u > 1 - \epsilon, \tag{2.2.1b}$$

for some number ϵ with $0 < \epsilon < 1/2$. The maps f_0, f_1 are called homotopic when they are related by a homotopy. If f_0, f_1 and the h_u are all embeddings, then h is called an isotopy and f_0, f_1 are called isotopic.

Manifolds and maps and manifolds and maps up to homotopy form categories.

There is a stronger notion of homotopy, called ambient isotopy.

Definition 2.2.2 *Let M, N be manifolds and let $f_0,\ f_1 : N \to M$ be maps. An ambient isotopy of f_0, f_1 with sitting instants is a smooth family F_u, $u \in \mathbb{R}$, of autodiffeomorphisms of M with the property that*

$$F_u = \mathrm{id}_M \qquad \text{for } u < \epsilon, \tag{2.2.2a}$$

$$F_u = F_1 \qquad \text{for } u > 1 - \epsilon, \tag{2.2.2b}$$

for some number ϵ with $0 < \epsilon < 1/2$ and that

$$f_1 = F_1 \circ f_0. \tag{2.2.3}$$

The maps f_0, f_1 are called ambient isotopic when they are related by an ambient isotopy.

The requirement that homotopies and isotopies have sitting instants is not necessary strictly speaking. We have introduced it for the sake of a more uniform formulation. All homotopies and isotopies considered in this paper will be assumed to have sitting instants unless otherwise stated.

We provide next a formulation of ordinary knot theory based on the smooth set–up of subsect. 2.1. Proceeding along the same lines, we shall then construct a full–fledged formulation of surface knot theory relying on the same framework.

Let C be an oriented differentiable closed curve, that is a circle.

Definition 2.2.3 *A pointing of* C *consists in a distinguished point* p_C *of* C*.*

Below, we shall assume that C is equipped with a fixed pointing.

Definition 2.2.4 *A free* C*–knot* ξ *of* M *is an embedding* $\xi : C \to M$*.*

The image $\xi(C)$ of a free C–knot ξ is a differentiable closed curve in M with the orientation induced by that of C via the embedding. The image of ξ should not be confused with ξ itself.

Ambient isotopy of free C–knots is defined in the obvious fashion.

Definition 2.2.5 *Two free* C*–knot* ξ_0*,* ξ_1 *of* M *are ambient isotopic if they are as embeddings of* C *into* M*.*

So, if F is the ambient isotopy transforming ξ_0 into ξ_1, then

$$\xi_1 = F_1 \circ \xi_0. \tag{2.2.4}$$

Ambient isotopy of free C–knots is an equivalence relation. We denote the set of all ambient isotopy classes of free C–knots by $\mathrm{Knot}_{\mathrm{F}C}(M)$.

The basic constructions with knots we are going to introduce work for based knots. This requires that a C–pointing on the target manifold M be given.

Definition 2.2.6 *A manifold* M *is called* C*–pointed, if a distinguished point* p_M *of* M *is specified.*

In common parlance, M is called pointed. Clearly, C itself is C–pointed.

Definition 2.2.7 *Let M, N be C–pointed manifolds and let $f : N \to M$ be a map. f is said to be C–pointing preserving if*

$$f(p_N) = p_M. \tag{2.2.5}$$

In usual terms, f is a pointed map. One defines in analogous fashion C–pointing preserving diffeomorphisms, autodiffeomorphisms etc.

Definition 2.2.8 *Let M, N be C–pointed manifolds and let f_0, $f_1 : N \to M$ be C–pointing preserving maps. A C–pointing preserving homotopy h of f_0, f_1 is an ordinary homotopy of f_0, f_1 such that the maps $h_y : N \to M$, $y \in \mathbb{R}$, are all C–pointing preserving,*

$$h_y(p_N) = p_M. \tag{2.2.6}$$

The C–pointing preserving maps f_0, f_1 are called homotopic, if they are related by a C–pointing preserving homotopy. If f_0, f_1 and the h_y are all embeddings, h is called a C–pointing preserving isotopy and f_0, f_1 are said isotopic.

C–pointed manifolds and C–pointing preserving maps form a category. C–pointed manifolds and C–pointing preserving maps up to C–pointing preserving homotopy constitute also a category.

Definition 2.2.9 *Let M, N be C–pointed manifolds and let f_0, $f_1 : N \to M$ be C–pointing preserving maps. A C–pointing preserving ambient isotopy of f_0, f_1 is an ordinary ambient isotopy of f_0, f_1 such that the autodiffeomorphisms F_y, $y \in \mathbb{R}$, are all C–pointing preserving,*

$$F_y(p_M) = p_M. \tag{2.2.7}$$

The C–pointing preserving maps f_0, f_1 are called ambient isotopic, if they are related by an C–pointing preserving ambient isotopy.

Given a C–pointed manifold M, we can define C–knots.

Definition 2.2.10 *A C–knot of M in the C–pointed manifold M is a C–pointing preserving embedding $\xi : C \to M$.*

A C–knot ξ is thus based in that

$$\xi(p_C) = p_M. \tag{2.2.8}$$

A C–knot ξ is also a free C–knot, if one forgets the C–pointing of M. Conversely, a free C–knot ξ is secretly a C–knot belonging to the C–pointing $p_M = \xi(p_C)$ of M. We note that id_C is a C–knot of C, called tautological C–knot.

We want to identify knots related by an appropriate form of ambient isotopy.

Definition 2.2.11 *Two C–knot ξ_0, ξ_1 in the C–pointed manifold M are ambient isotopic if they are as embeddings of C into M via a C–pointing preserving ambient isotopy.*

If two C–knots are ambient isotopic, they also are as free C–knots. The converse is clearly generally false. Ambient isotopy of C–knots is an equivalence relation. We denote by $\mathrm{Knot}_C(M)$ the set of all ambient isotopy classes of C–knots.

We shall now describe knots in terms of curves and (thin) homotopy thereof (cf. subsect. 2.1).

Definition 2.2.12 *A curve γ_C of C is said to be compatible with the pointing of C, if $\gamma_C : p_C \to p_C$ and $I_C = {\gamma_C}^{-1}(C \setminus p_C)$ is an open interval of $\mathbb{R}$ such that $\gamma_C\big|_{I_C}$ is an orientation preserving diffeomorphism onto $C \setminus p_C$.*

It γ_C is compatible, then

$$\gamma_C(x) = p_C \qquad \text{for } x < \epsilon, \tag{2.2.9a}$$

$$\gamma_C(x) = p_C \qquad \text{for } x > 1 - \epsilon, \tag{2.2.9b}$$

for some number ϵ with $0 < \epsilon < 1/2$, by (2.1.1). Further, the interval I_C is contained in the open interval $(\epsilon, 1-\epsilon)$ and $\gamma_C\big|_{I_C}$ provides a one–to-one parametrization of $C \setminus p_C$ consistent with its orientation.

Fix a curve γ_C of C compatible with the pointing of C. Given a C–knot ξ, one can push–forward the curve $\gamma_C : p_C \to p_C$ of C by the map $\xi : C \to M$ yielding a curve $\xi \circ \gamma_C : p_M \to p_M$ of M.

Definition 2.2.13 *For a C–knot ξ, let $\gamma_\xi : p_M \to p_M$ be the curve of M*

$$\gamma_\xi = \xi \circ \gamma_C. \tag{2.2.10}$$

By (2.2.9a), (2.2.9b), γ_ξ satisfies

$$\gamma_\xi(x) = p_M \qquad \text{for } x < \epsilon, \tag{2.2.11a}$$

$$\gamma_\xi(x) = p_M \qquad \text{for } x > 1-\epsilon, \tag{2.2.11b}$$

for the same number ϵ as in (2.2.9). Further, by the compatibility of γ_C, $\gamma_\xi\big|_{I_C}$ furnishes a one–to-one parametrization of $\xi(C) \setminus p_M$ consistent with its orientation. We notice also that the curve γ_C is nothing but the curve γ_{id_C} of C of the tautological C–knot id_C.

The curve γ_ξ associated with a C–knot ξ enjoys several properties of invariance up to (thin) homotopy.

Proposition 2.2.1 *For any C–knot ξ of M, the curve γ_ξ is independent from the choice of the compatible curve γ_C of C up to thin homotopy.*

Proof. Fix an oriented differentiable universal covering $\tilde{C}$ of C with orientation preserving covering map $\varpi_C : \tilde{C} \to C$.

Let γ_C be a curve of C compatible with the pointing of C. Since γ_C is a map $\gamma_C : \mathbb{R} \to C$ with a simply connected domain, there is a lifting map $\tilde{\gamma}_C : \mathbb{R} \to \tilde{C}$ such that $\varpi_C \circ \tilde{\gamma}_C = \gamma_C$ unique up to left composition by orientation preserving deck diffeomorphisms of $\tilde{C}$. The compatibility of γ_C (cf. def. 2.2.12) implies further that there is an open subset $\tilde{F}_C$ of $\tilde{C}$ with the following properties. First, $\tilde{F}_C$ is the interior of a simply connected fundamental domain of the universal covering $\tilde{C}$. Second, $\tilde{\gamma}_C$ is a map of $\mathbb{R}$ onto $\overline{\tilde{F}}_C$ and $\tilde{\gamma}_C\big|_{I_C}$ is an orientation preserving diffeomorphism of I_C onto $\tilde{F}_C$. Third, $\varpi_C\big|_{\tilde{F}_C}$is an orientation preserving diffeomorphism of $\tilde{F}_C$ onto the image of $\gamma_C\big|_{I_C}$. The fact that γ_C expresses a curve $\gamma_C : p_C \to p_C$ implies then that $\tilde{\gamma}_C$ similarly expresses a curve $\tilde{\gamma}_C : \tilde{p}_C \to \tilde{p}_C{}'$, where $\tilde{p}_C$, $\tilde{p}_C{}'$ are points of $\tilde{C}$ such that $\varpi(\tilde{P}_C) = \varpi_C(\tilde{p}_C{}') = p_C$. As $\tilde{F}_C$ can be taken independent from γ_C by the deck symmetry, $\tilde{p}_C$, $\tilde{p}_C{}'$ also can.

Concretely, modelling C as $\mathbb{R}/\mathbb{Z}$, $\tilde{C}$ as $\mathbb{R}$ and ϖ_C as the quotient map of $\mathbb{R}$ modulo $\mathbb{Z}$ and taking $\tilde{p}_C = 0$, $\tilde{p}_C{}' = 1$, we can think of $\tilde{\gamma}_C$ as a surjective map $\tilde{\gamma}_C : \mathbb{R} \to [0, 1]$ that is strictly increasing on I_C.

Let γ_{C0}, γ_{C1} be two curves of C compatible with the pointing of C. Let $\tilde{\gamma}_{C0}$, $\tilde{\gamma}_{C1}$ be the curves of $\tilde{C}$ lifting γ_{C0}, γ_{C1}, respectively. From the remarks of the previous paragraph, it follows that there is a map $\tilde{h} : \mathbb{R}^2 \to \tilde{C}$ satisfying conditions (2.1.5) with $p_0 = \tilde{p}_C$, $p_1 = \tilde{p}_C{}'$ and $\gamma_0 = \gamma_{C0}$, $\gamma_1 = \gamma_{C1}$. By mere dimensional reasons, condition (2.1.6) is fulfilled as well. Hence, $\tilde{h}$ is a thin homotopy of $\tilde{\gamma}_{C0}$, $\tilde{\gamma}_{C1}$. So, $h = \varpi_C \circ \tilde{h} : \mathbb{R}^2 \to C$ is a thin homotopy of γ_{C0}, γ_{C1}.

As γ_{C0}, γ_{C1} are thin homotopic, for any C–knot ξ, $\xi \circ \gamma_{C0}$, $\xi \circ \gamma_{C1}$ also are. The statement follows. □

Ambient isotopic C–knots yield homotopic curves, as it is natural.

Proposition 2.2.2 *If two C–knots ξ_0, ξ_1 of M are ambient isotopic, then there exists a homotopy $h : \gamma_{\xi_0} \Rightarrow \gamma_{\xi_1}$.*

Proof. Let F_y, $y \in \mathbb{R}$, be a C–pointing preserving ambient isotopy relating the knots ξ_0, ξ_1. Define a map $h : \mathbb{R}^2 \to M$ by

$$h(x, y) = F_y \circ \gamma_{\xi_0}(x). \tag{2.2.12}$$

Using relations (2.2.11) together with (2.2.2) and (2.2.4), it is readily checked that h satisfies the relations (2.1.5) with $p_0 = p_1 = p_M$ and $\gamma_0 = \gamma_{\xi_0}$, $\gamma_1 = \gamma_{\xi_1}$. It follows that (2.2.12) defines a homotopy $h : \gamma_{\xi_0} \Rightarrow \gamma_{\xi_1}$. $\square$

As a consequence, the curve γ_ξ depends only on the ambient isotopy class of the knot ξ up to homotopy and the map $\xi \to \gamma_\xi$ descends to one from $\mathrm{Knot}_C(M)$ to set of the curves of M mod homotopy.

So far, we have considered C–knots belonging to a fixed C–pointing of M. In view of topological applications, it is however necessary to compare C–knots belonging to possibly distinct C–pointings. As before, these knots will be topologically equivalent if they are ambient isotopic. Since C–pointing preservation is now necessarily violated, the form of ambient isotopy involved here is more general than the one considered up to this point. We call it free for to comply with customary terminology. Prop. 2.2.2 extends also to freely ambient isotopic C–knots in a form which we shall make precise next.

When several C–pointings p_{M0}, p_{M1}, ... of M are given, we shall denote the C–pointed manifold M by M_0, M_1, ... and shall call the C–knots ξ of M as C–knots of M_0, M_1, ..., respectively.

Suppose we are given two possibly distinct C–pointings p_{M0}, p_{M1} of M.

Definition 2.2.14 *Two C–knots ξ_0, ξ_1 of M_0, M_1, respectively, are called freely ambient isotopic if they are related by an ambient isotopy W.*

We stress that, when the pointings are equal, free ambient isotopy does not reduce to ambient isotopy, since it is not required to be C–pointing preserving.

We consider now two C–knots ξ_0, ξ_1 of M_0, M_1, respectively, which are freely ambient isotopic. If W is the underlying connecting ambient isotopy, ξ_0, ξ_1 are then related by definition as

$$\xi_1 = W_1 \circ \xi_0. \tag{2.2.13}$$

In virtue of (2.2.8), p_{M0}, p_{M1} are related accordingly,

$$p_{M1} = W_1(p_{M0}). \tag{2.2.14}$$

These relations suggest using the isotopy W to construct a smooth family p_{My} of C–pointings interpolating p_{M0}, p_{M1} and a smooth family ξ_y of C–knots of M_y interpolating ξ_0, ξ_1. To carry this out, we pick a non decreasing smooth function $\alpha : \mathbb{R} \to [0,1]$ such that $\alpha(u) = 0$ for $u < \epsilon$ and $\alpha(u) = 1$ for $u > 1-\epsilon$, where $0 < \epsilon < 1/2$ such that the (2.2.9) hold.

Definition 2.2.15 *For $y \in \mathbb{R}$, let p_{My} be the C–pointing of M given by*

$$p_{My} = W_{\alpha(y)}(p_{M0}). \tag{2.2.15}$$

We note that $p_{My} = p_{M0}$ for $y < \epsilon$ and $p_{My} = p_{M1}$ for $y > 1-\epsilon$, where p_{M0} and p_{M1} are the two given C–pointings.

Definition 2.2.16 *For $y \in \mathbb{R}$, let ξ_y be the C–knot of M_y given by*

$$\xi_y = W_{\alpha(y)} \circ \xi_0. \tag{2.2.16}$$

Property (2.2.8) is immediately checked. We note that $\xi_y = \xi_0$ for $y < \epsilon$ and $\xi_y = \xi_1$ for $y > 1-\epsilon$, where here ξ_0 and ξ_1 stand for the two given knots.

Using the interpolating setup just introduced, one can prove the following proposition.

Proposition 2.2.3 *Let ξ_0, ξ_1 be C–knots of M_0, M_1, respectively. Assume further that ξ_0, ξ_1 are freely ambient isotopic. Then, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and a homotopy $h : \gamma_{\xi_0} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{\xi_1} \circ \gamma_1$.*

As composition of curves is non associative, in a multiple composition of curves we have to fix the sequential order in which the single compositions are performed.

Here and in the following, we tacitly apply the "compose the rightmost first" convention: we compose first the rightmost and next to rightmost curve, then the result with the next to next to rightmost curve and so on. Any other choice of convention leads to a curve that is thin homotopic to the one obtained in this way.

Proof. As y varies, the point p_{My} traces a differentiable curve in M. Conjoined with this is a family of curves $\gamma_y : p_{M0} \to p_{My}$ of M given by

$$\gamma_y(x) = W_{\alpha(x)\alpha(y)}(p_{M0}). \tag{2.2.17}$$

This has the property that $\gamma_y = \iota_{p_{M0}}$ for $y < \epsilon$ and $\gamma_y = \gamma_1$ for $y > 1 - \epsilon$.

With the C–knot ξ_y, there is associated the curve γ_{ξ_y} according to (2.2.10). By composing successively the curves $\gamma_y : p_{M0} \to p_{My}$, $\gamma_{\xi_y} : p_{My} \to p_{My}$ and ${\gamma_y}^{-1\circ} : p_{My} \to p_{M0}$, we obtain a curve $\widehat{\gamma}_{\xi_y} : p_{M0} \to p_{M0}$, viz

$$\widehat{\gamma}_{\xi_y} = {\gamma_y}^{-1\circ} \circ \gamma_{\xi_y} \circ \gamma_y. \tag{2.2.18}$$

For continuously varying y, the curve $\widehat{\gamma}_{\xi_y}$ shifts from the curve $\widehat{\gamma}_{\xi_0}$ to that $\widehat{\gamma}_{\xi_1}$ yielding a homotopy $\widehat{h} : \widehat{\gamma}_{\xi_0} \Rightarrow \widehat{\gamma}_{\xi_1}$. Indeed, as a map $\widehat{h} : \mathbb{R}^2 \to M$, $\widehat{h}$ is given by

$$\widehat{h}(x, y) = \widehat{\gamma}_{\xi_y}(x). \tag{2.2.19}$$

By the properties of the curves γ_{ξ_y} and γ_y and (2.2.19), it is evident that $\widehat{h}$ is smooth and it is readily verified that $\widehat{h}$ satisfies the (2.1.5) with $p_0 = p_1 = p_{M0}$, $\gamma_0 = \widehat{\gamma}_{\xi_0}$, $\gamma_1 = \widehat{\gamma}_{\xi_1}$ and perhaps a different value of ϵ.

By (2.2.18), the source and target curves of $\widehat{h}$ explicitly are $\widehat{\gamma}_{\xi_0} = {\iota_{p_{M0}}}^{-1\circ} \circ \gamma_{\xi_0} \circ \iota_{p_{M0}}$ and $\widehat{\gamma}_{\xi_1} = {\gamma_1}^{-1\circ} \circ \gamma_{\xi_1} \circ \gamma_1$. Since ${\iota_{p_{M0}}}^{-1\circ} \circ \gamma_{\xi_0} \circ \iota_{p_{M0}}$ is thin homotopic to γ_{ξ_0} itself, $\widehat{h}$ induces a homotopy $h : \gamma_{\xi_0} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{\xi_1} \circ \gamma_1$. □

Since a free C–knot ξ is a C–knot belonging to the C–pointing $\xi(p_C)$ of M, we can construct the associated curve $\gamma_\xi : \xi(p_C) \to \xi(p_C)$ as detailed above.

The curve γ_ξ of a free C–knot ξ depends on the the pointing p_C of C, which up to this point we have tacitly assumed to be fixed, while ξ as a mere embedding of C into M does not. Of course, there are infinitely many choices of p_C and any particular one is merely conventional. To be natural, our construction should be independent from the choice made in a suitable sense. The following analysis is in order.

When several pointings p_{C0}, p_{C1}, $\ldots$ of C are envisaged, we shall denote C by C_0, C_1, $\ldots$, call a target C–pointed manifold M a C_0–, C_1–, $\ldots$ pointed manifold and the C–knots ξ it supports C_0–, C_1–, $\ldots$ knots, respectively, to indicate which pointing of C is referred to.

Suppose that two pointings p_{C0} and p_{C1} of C are given and that the manifold M is C_0– and C_1– pointed by p_{M0}, p_{M1}, respectively. Suppose further that ξ is simultaneously a C_0–knot of M_0 and a C_1–knot of M_1. The natural question arises about the relation between the curves $\gamma_{0\xi}$, $\gamma_{1\xi}$ associated with ξ in the two pointings. The following proposition provides a simple answer to it.

Proposition 2.2.4 *If ξ is at the same time a C_0–knot of M_0 and a C_1–knot of M_1, then there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and a thin homotopy $h : \gamma_{0\xi} \Rightarrow \gamma_1{}^{-1_\circ} \circ \gamma_{1\xi} \circ \gamma_1$, both with image contained in that of ξ.*

Proof. To build the curves $\gamma_{0\xi}$, $\gamma_{1\xi}$, compatible curves γ_{C0}, γ_{C1} of C_0, C_1, respectively, must be picked. By prop. 2.2.1, $\gamma_{0\xi}$, $\gamma_{1\xi}$ are independent from the choice of γ_{C0}, γ_{C1} up to thin homotopy. This allows us to assume a convenient relationship between γ_{C0}, γ_{C1}. We choose γ_{C0}, γ_{C1} satisfying $\gamma_{C1} = f \circ \gamma_{C0}$, where f is an orientation preserving autodiffeomorphism of C such that $p_{C1} = f(p_{C0})$.

The composition $\xi \circ f$ is a C_0–knot of M_1. Since C is the circle manifold which has no isotopically non trivial orientation preserving autodiffeomorphisms, the autodiffeomorphisms f is necessarily isotopic to id_C. There is thus an orientation preserving isotopy k_y, $y \in \mathbb{R}$, deforming id_C into f. The composition $\xi \circ k_y$ defines then an isotopy of the C_0–knots ξ and $\xi \circ f$. By the isotopy extension theorem, there is an ambient isotopy W_y, $y \in \mathbb{R}$, of ξ and $\xi \circ f$ such that $W_y \circ \xi = \xi \circ k_y$. The C_0–knots ξ, $\xi \circ f$ are thus freely ambient isotopic.

By prop. 2.2.3 with $\xi_0 = \xi$, $\xi_1 = \xi \circ f$, there is then a homotopy $h : \gamma_{0\xi} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{0\xi\circ f} \circ \gamma_1$, where $\gamma_1 : p_{M0} \to p_{M1}$ is a curve of M. By (2.2.10), as $\gamma_{C1} = f \circ \gamma_{C0}$, $\gamma_{1\xi} = \gamma_{0\xi\circ f}$. The above is thus also a homotopy $h : \gamma_{0\xi} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{1\xi} \circ \gamma_1$. As explained in the proof of prop. 2.2.3, the homotopy h is the composition of the standard thin homotopy $\gamma_{0\xi} \Rightarrow {\iota_{p_{M0}}}^{-1\circ} \circ \gamma_{0\xi} \circ \iota_{p_{M0}}$ and the homotopy $\widehat{h} : {\iota_{p_{M0}}}^{-1\circ} \circ \gamma_{0\xi} \circ \iota_{p_{M0}} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{1\xi} \circ \gamma_1$ defined by (2.2.18), (2.2.19), here with γ_{ξ_y} replaced by $\gamma_{0\xi_y}$. The curves γ_y and $\gamma_{0\xi_y}$ entering in (2.2.18) are given by (2.2.16), (2.2.17), where W is the free ambient isotopy introduced in the previous paragraph. Since $W_y \circ \xi = \xi \circ k_y$, we have $\gamma_y(x) = W_{\alpha(x)\alpha(y)}(\xi(p_{C0})) = \xi(k_{\alpha(x)\alpha(y)}(p_{C0}))$ and $\gamma_{0\xi_y}(x) = W_{\alpha(y)}(\xi(\gamma_{C0}(x))) = \xi(k_{\alpha(y)}(\gamma_{C0}(x)))$. Thus, the images of γ_y and $\gamma_{0\xi_y}$ are contained in that of ξ. As this latter is a differentiable curve in M, $\widehat{h}$ satisfies (2.1.6) for dimensional reasons. $\widehat{h}$ is hence a thin homotopy. It follows that h is a thin homotopy. By the above property of the curves γ_y, $\gamma_{0\xi_y}$, the images of the curve γ_1 and homotopy h lie in that of the knot ξ. $\square$

Inspired by the theory of ordinary knots expounded above, we are now ready to formulate its extension to surface knots.

To construct surface knot theory, we need a slight generalization of the notion of (free) C–knot given above which does not require full smoothness.

Assume that C is endowed with a pointing p_C.

Definition 2.2.17 *A spiky free C–knot of M is a topological embedding $\xi : C \to M$ that is smooth on $C \setminus p_C$ and has the following properties.*

1. *The jets of any order of ξ have finite limits at both ends of $C \setminus p_C$.*
2. *The jet of order 1 of ξ has non zero limits at both ends of $C \setminus p_C$.*

The regularity conditions at p_C ensure that ξ has a well defined tangent vector at each end of $C \setminus p_C$ and that with ξ there can be associated a curve γ_ξ of M as for a C–knot. Every free C–knot is also a spiky free C–knot, while not every spiky free C–knot is a free C–knot.

Suppose now that the manifold M is C–pointed by p_M.

Definition 2.2.18 *A spiky C–knot of M is a C–pointing preservation topological embedding $\xi : C \rightarrow M$ satisfying the same regularity conditions as a spiky free C–knot.*

The property of C pointing preservation has again the statement (2.2.8). Compare with def. 2.2.10. Every C–knot is also a spiky C–knot, while not every spiky C–knot is a C–knot.

Let γ_C be a curve of C compatible with the pointing of C (cf. def. 2.2.12).

Definition 2.2.19 *For a spiky C–knot ξ of M, let $\gamma_\xi : p_M \rightarrow p_M$ be the curve of M defined by* (2.2.10).

Compare with def. 2.2.13. The curve γ_ξ of a spiky C–knot enjoys the same properties as that of a C–knot. In particular, the (2.2.11) hold.

Let S be an oriented differentiable closed surface of genus ℓ_S, that is a sphere with ℓ_S handles.

Definition 2.2.20 *A marking of S consists of:*

1. *a C–pointing p_S of S;*
2. *$2\ell_S$ spiky C–knots ζ_{Si} of S with the following properties.*
3. *The sets $\zeta_{Si}(C)$ pairwise intersect only at p_S.*
4. *The ζ_{Si} represent the $2\ell_S$ homotopy classes of the standard oriented a– and b–cycles of S.*

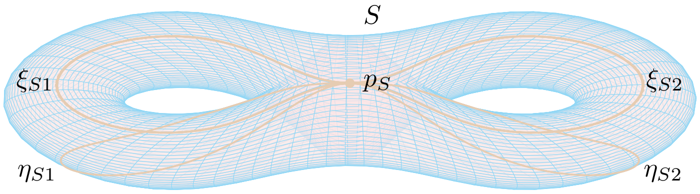

Figure 1: The surface S with the C–knots ξ_{Sr}, η_{Sr} shown. Here, $\ell_S = 2$.

For a given index i, the knot ζ_{Si} will be denoted also as ξ_{Sr} or η_{Sr} according to whether it corresponds to the r–th a– or b–cycle, respectively. See. fig. 1. For $\ell_S = 0$, the ζ_{Si} are absent. Below, we assume that S is equipped with a marking fixed once and for all.

Definition 2.2.21 *A free S–surface knot Ξ of M is an embedding $\Xi : S \to M$.*

The image of $\Xi(S)$ of a free S–surface knot Ξ is a differentiable closed surface of M with the orientation induced by that of S via the embedding. The image of Ξ should not be confused with Ξ itself.

Ambient isotopy of free S–surface knots is defined in the obvious fashion.

Definition 2.2.22 *Two free S–surface knot Ξ_0, Ξ_1 of M are ambient isotopic if they are as embeddings of S into M.*

Hence, if F is the ambient isotopy transforming Ξ_0 into Ξ_1, then

$$\Xi_1 = F_1 \circ \Xi_0. \tag{2.2.20}$$

Ambient isotopy of free S–surface knots is an equivalence relation. We denote the set of all ambient isotopy classes of free S–surface knots by $\mathrm{Knot}_{\mathrm{F}S}(M)$.

Definition 2.2.23 *For any free S–surface knot $\varXi$, the spiky free C–knots*

$$ {\zeta_{Si}}^* \varXi = \varXi \circ \zeta_{Si} \tag{2.2.21} $$

are called the characteristic C–knots of $\varXi$.

Ambient isotopic surface knots have ambient isotopic characteristic C–knots.

Proposition 2.2.5 *Let $\varXi_0$, $\varXi_1$ be two ambient isotopic free S–surface knots of M. Then, their characteristic C–knots ${\zeta_{Si}}^* \varXi_0$, ${\zeta_{Si}}^* \varXi_1$ are ambient isotopic.*

Proof. This is an immediate consequence of (2.2.20) and (2.2.21). □

If F is the ambient isotopy turning $\varXi_0$ into $\varXi_1$, then

$$ {\zeta_{Si}}^* \varXi_1 = F_1 \circ {\zeta_{Si}}^* \varXi_0. \tag{2.2.22} $$

As for ordinary knots, the basic constructions with surface knots we are going to introduce work for based surface knots.

Definition 2.2.24 *A manifold M is said S–marked when the following data are specified:*

1. *a C–pointing p_M of M;*
2. *$2\ell_S$ spiky C–knots ζ_{Mi} of M with the following property.*
3. *The sets $\zeta_{Mi}(C)$ pairwise intersect only at p_M.*

For a given index i, the knot ζ_{Mi} will be denoted also as ξ_{Mr} or η_{Mr} according to whether the knot ζ_{Si} equals ξ_{Sr} or η_{Sr} in S as detailed above, respectively. For $\ell_S = 0$, the knots ζ_{Mi} are absent. Note that the differentiable surface S itself is S–marked.

Definition 2.2.25 *Let M, N be S–marked manifolds and let $f : N \to M$ be a* *map. f is said S–marking preserving if*

$$f(p_N) = p_M, \tag{2.2.23a}$$

$$f \circ \zeta_{Ni} = \zeta_{Mi}. \tag{2.2.23b}$$

One defines analogously S–marking preserving diffeomorphisms, autodiffeomorphisms etc. For $\ell_S > 0$, (2.2.23a) follows from (2.2.23b) upon evaluation at p_C. By (2.2.23a), f is C–pointing preserving.

Definition 2.2.26 *Let M, N be S–marked manifolds and let f_0, $f_1 : N \to M$ be S–marking preserving maps. An S–marking preserving homotopy h of f_0, f_1 is an ordinary homotopy of f_0, f_1 such that the maps $h_z : N \to M$, $z \in \mathbb{R}$, are all S–marking preserving,*

$$h_z(p_N) = p_M, \tag{2.2.24a}$$

$$h_z \circ \zeta_{Ni} = \zeta_{Mi}. \tag{2.2.24b}$$

The S–marking preserving maps f_0, f_1 are said homotopic when they are related by S–marking preserving homotopy. If f_0, f_1 and the h_z are all embeddings, then h is called an S–marking preserving isotopy and f_0, f_1 are said isotopic.

S–marked manifolds and S–marking preserving maps form a category. S–marked manifolds and S–marking preserving maps up to S–marking preserving homotopy constitute also a category.

Definition 2.2.27 *Let M, N be S–marked manifolds and let f_0, $f_1 : N \to M$ be S–marking preserving maps. An S–marking preserving ambient isotopy of f_0, f_1 is an ordinary ambient isotopy of f_0, f_1 such that the autodiffeomorphisms F_z, $z \in \mathbb{R}$, are all S–marking preserving ,*

$$F_z(p_M) = p_M, \tag{2.2.25a}$$

$$F_z \circ \zeta_{Mi} = \zeta_{Mi}. \tag{2.2.25b}$$

The S–marking preserving maps f_0, f_1 are said ambient isotopic when they are related by an S–marking preserving ambient isotopy.

Given an S–marked manifold M, we can define S–surface knots, which are a higher analogue of ordinary based knots.

Definition 2.2.28 *An S–surface knot in the S–marked manifold M is an S–marking preserving embedding $\varXi : S \to M$.*

A S–surface knot $\varXi$ is based in that

$$\varXi(p_S) = p_M, \tag{2.2.26a}$$

$$\varXi \circ \zeta_{Si} = \zeta_{Mi}. \tag{2.2.26b}$$

An S–surface knot $\varXi$ is also a free S–surface knot, if one forgets the S–marking of M. Conversely, a free S–surface knot $\varXi$ is secretly an S–surface knot belonging to the S–marking $\{p_M = \varXi(p_S), \zeta_{Mi} = {\zeta_{Si}}^*\varXi\}$ of M. id_S is an S–surface knot of S, the tautological S–surface knot.

Clearly, by (2.2.26b), the characteristic C–knots ${\zeta_{Si}}^*\varXi$ of an S–surface knots $\varXi$ belonging an S–marking of M $\{p_M, \zeta_{Mi}\}$ of M belong to the C–pointing p_M of M and are equal to ζ_{Mi}.

It is important to stress that, while an S–marking of M of genus $\ell_S = 0$ always supports S–surface knots, for a given S–marking of M of genus $\ell_S > 0$, there may exist no S–surface knots at all, as in the latter case, for generic C–knots ζ_{Mi}, (2.2.26b) may be incompatible with the ζ_{Si} representing the $2\ell_S$ homotopy classes of the standard oriented a– and b–cycles of S and $\varXi$ being an embedding of S in M. By contrast, for every C–pointing, there always are C–knots belonging to it.

Definition 2.2.29 *An S–marking of M is called admissible if there exists at least one S–surface knot.*

All S–markings considered in the following will be tacitly assumed to be admissible unless otherwise stated.

We want to identify surface knots related by an appropriate form of ambient isotopy, which we define next.

Definition 2.2.30 *Two S–surface knot $\varXi_0$, $\varXi_1$ in the S–marked manifold M are ambient isotopic if they are as embeddings of S into M via an S–marking preserving ambient isotopy.*

Ambient isotopy of S–surface knots is an equivalence relation. We denote by $\mathrm{Knot}_S(M)$ the set of all ambient isotopy classes of S–surface knots.

Let us now see whether it is possible to describe surface knots using curves, surfaces and (thin) homotopy thereof (cf. subsect. 2.1).

To begin with, we fix a curve γ_C of C compatible with the pointing of C to construct the curves associated with spiky C–knots.

The curves of the spiky C–knots of the marking of S are constructed according the prescription (2.2.10). We have

$$\gamma_{Si} = \gamma_{\zeta_{Si}} \tag{2.2.27}$$

Correspondingly, we set

$$\alpha_{Sr} = \gamma_{\xi_{Sr}}, \qquad \beta_{Sr} = \gamma_{\eta_{Sr}}, \tag{2.2.28}$$

when we sort the knots ζ_{Si} according to their correspondence to the a– and b–cycles of S. Next, we now define a curve $\tau_S : p_S \to p_S$ of S by

$$\tau_S = {\beta_{S\ell_S}}^{-1\circ} \circ {\alpha_{S\ell_S}}^{-1\circ} \circ \beta_{S\ell_S} \circ \alpha_{S\ell_S} \circ \cdots \circ {\beta_{S1}}^{-1\circ} \circ {\alpha_{S1}}^{-1\circ} \circ \beta_{S1} \circ \alpha_{S1} \tag{2.2.29}$$

(cf. fig. 2). The "compose the rightmost first" convention for multiple composition of curves is tacitly applied here and in the following. When $\ell_S = 0$, we set conventionally that $\tau_S = \iota_{p_S}$.

Definition 2.2.31 *A surface Σ_S is said to be compatible with the marking of S, if $\Sigma_S : \iota_{p_S} \Rightarrow \tau_S$ and $D_S = {\Sigma_S}^{-1}(S \setminus \cup_i \zeta_{Si}(C))$ is an open simply connected domain of $\mathbb{R}^2$ such that $\Sigma_S\big|_{D_S}$ is an orientation preserving diffeomorphism onto $S \setminus \cup_i \zeta_{Si}(C)$.*

If Σ_S is compatible, then

$$\Sigma_S(x,y) = p_S \qquad \text{for } x < \epsilon, \tag{2.2.30a}$$

$$\Sigma_S(x,y) = p_S \qquad \text{for } x > 1-\epsilon, \tag{2.2.30b}$$

$$\Sigma_S(x,y) = p_S \qquad \text{for } y < \epsilon, \tag{2.2.30c}$$

$$\Sigma_S(x,y) = \tau_S(x) \qquad \text{for } y > 1-\epsilon \tag{2.2.30d}$$

for some number ϵ with $0 < \epsilon < 1/2$, by (2.1.8a)–(2.1.8d), where we used that $\iota_{p_S}(x) = p_S$. Further, the domain D_S is contained in the open square $(\epsilon, 1-\epsilon)^2$ and $\Sigma_S\big|_{D_S}$ provides a one–to-one parametrization of $S \setminus \cup_i \zeta_{Si}(C)$ consistent with its orientation.

It is important to realize that, in high genus, the choice of a compatible surface

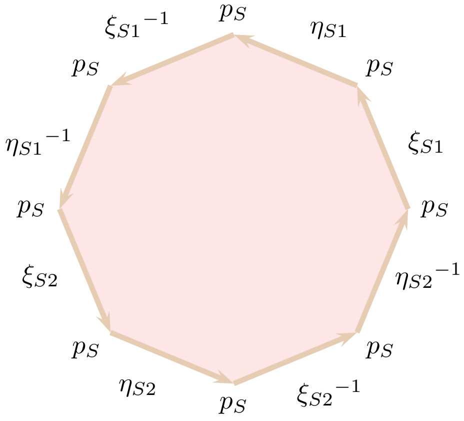

Figure 2: The surface S unfolds upon being cut along the C–knots ξ_{Sr}, η_{Sr}. Here, $\ell_S = 2$.

$\varSigma_S$ of S involves a prior choice of a compatible curve γ_C of C.

Definition 2.2.32 *A choice of a surface $\varSigma_S$ of S compatible with the marking of S is said congruent with one of a curve γ_C of C compatible with the pointing of C if either $\ell_S = 0$ or $\ell_S > 0$ and τ_S is expressed by* (2.2.29) *with the curves α_{Sr}, β_{Sr} defined through* (2.2.10) *and* (2.2.28) *in terms of γ_C.*

Fix a surface $\varSigma_S$ of S compatible with the marking of S and congruent with the chosen compatible curve γ_C. Below, we shall tacitly assume that the value of the number ϵ appearing in the (2.2.9) and (2.2.30) has been adjusted so that the (2.2.9) and (2.2.30) simultaneously hold.

Next, we construct the curves of the spiky C–knots ζ_{Mi} of the S–marked manifold M using again the prescription (2.2.10). We set

$$\gamma_{Mi} = \gamma_{\zeta_{Mi}} \tag{2.2.31}$$

Correspondingly, we set

$$\alpha_{Mr} = \gamma_{\xi_{Mr}}, \qquad \beta_{Mr} = \gamma_{\eta_{Mr}}, \tag{2.2.32}$$

when we sort the knots ζ_{Mi} according to their correspondence to the a– and b–cycles of S. We can define in this way a curve $\tau_M : p_M \to p_M$ of M by

$$\tau_M = {\beta_{M\ell_S}}^{-1\circ} \circ {\alpha_{M\ell_S}}^{-1\circ} \circ \beta_{M\ell_S} \circ \alpha_{M\ell_S} \circ \cdots \circ {\beta_{M1}}^{-1\circ} \circ {\alpha_{M1}}^{-1\circ} \circ \beta_{M1} \circ \alpha_{M1}. \tag{2.2.33}$$

When $\ell_S = 0$, $\tau_M = \iota_{p_M}$. τ_M clearly answers to τ_S and indeed it reduces to this latter when M is the S–marked manifold S.

Given an S–surface knot $\varXi$ of M, one can push–forward the surface $\varSigma_S : \iota_{p_S} \Rightarrow \tau_S$ of S by the map $\varXi : S \to M$. Since

$$\tau_M = \varXi \circ \tau_S \tag{2.2.34}$$

by (2.2.26b), we get a surface $\varXi \circ \varSigma_S : \iota_{p_M} \Rightarrow \tau_M$ of M.

Definition 2.2.33 *For an S–surface knot $\varXi$, let $\varSigma_\varXi : \iota_{p_M} \Rightarrow \tau_M$ be the surface of M defined as*

$$\varSigma_\varXi = \varXi \circ \varSigma_S. \tag{2.2.35}$$

By (2.1.8a)–(2.1.8d), we have

$$\varSigma_\varXi(x,y) = p_M \qquad \text{for } x < \epsilon, \tag{2.2.36a}$$

$$\varSigma_\varXi(x,y) = p_M \qquad \text{for } x > 1-\epsilon, \tag{2.2.36b}$$

$$\varSigma_\varXi(x,y) = p_M \qquad \text{for } y < \epsilon, \tag{2.2.36c}$$

$$\varSigma_\varXi(x,y) = \tau_M(x) \qquad \text{for } y > 1-\epsilon \tag{2.2.36d}$$

for the same number ϵ as in (2.2.30), where we used that $\iota_{p_M}(x) = p_M$. Further, by the compatibility of $\varSigma_S$, $\varSigma_\varXi\big|_{D_S}$ furnishes a one–to-one parametrization of $\varXi(S) \setminus \cup_i \zeta_{Mi}(C)$ consistent with its orientation. We note also that the surface $\varSigma_S$ is just the surface $\varSigma_{\mathrm{id}_S}$ of S associated with the tautological S–knot id_S.

At first glance, it would seem that the surface naturally associated with an S–surface knot $\varXi$ should be $\varSigma_\varXi$, since this appears to be the obvious counterpart of the curve γ_ξ associated with a C–knot ξ. Things are however a bit subtler and the reason why they are so is ultimately related to the end goal of the present construction, the use of flat connection holonomy and its homotopy invariance to study knot topology.

In ordinary knot theory, the curve γ_ξ associated with a C–knot ξ encodes the topological properties of ξ. It so provides also a measure of its non triviality. A generic C–knot ξ is non trivial to the extent to which its curve γ_ξ differs from the curve $\gamma_M = \gamma_{\xi_M}$ of a reference knot ξ_M, that is trivial according to topological knot theory. A measure of the triviality of ξ is then provided by the curve ratio ${\gamma^\sharp}_\xi = {\gamma_M}^{-1_\circ} \circ \gamma_\xi$.

Every C–pointing of M supports a canonical topologically trivial C–knot unique up to C–pointing preserving ambient isotopy, the unknot ξ_M, which is characterized by its image being the boundary of an embedded 2–dimensional disk. The curve $\gamma_M = \gamma_{\xi_M}$ associated with ξ_M is so equipped with a trivializing C–pointing preserving homotopy $k_M : \gamma_M \Rightarrow \iota_{p_M}$. For a C–knot ξ, the curve $\gamma^\sharp{}_\xi$ measuring its non triviality is thus homotopy equivalent to ${\iota_{p_M}}^{-1\circ} \circ \gamma_\xi$ through k_M and then to γ_ξ by the standard thin homotopy ${\iota_{p_M}}^{-1\circ} \circ \gamma_\xi \Rightarrow \gamma_\xi$. For the purpose of an evaluation of the non triviality of ξ, γ_ξ is hence as good as $\gamma^\sharp{}_\xi$.

Let us now examine to what extent the above consideration extend to higher knots. In surface knot theory, analogously to ordinary knot theory, the surface Σ_Ξ associated with an S–surface knot Ξ encodes the topological properties of Ξ. It so provides also a measure of its non triviality. A generic S–surface knot Ξ is non trivial inasmuch as its surface Σ_Ξ differs from the surface $\Sigma_M = \Sigma_{\Xi_M}$ of a reference knot Ξ_M, that is trivial according to some topological knot theoretic principle. A measure of the triviality of Ξ is then provided by the surface vertical ratio $\Sigma^\sharp{}_\Xi = {\Sigma_M}^{-1\bullet} \bullet \Sigma_\Xi$.

For genus $\ell_S = 0$, every S–marking of M supports a canonical topologically trivial S–surface knot unique up to S–marking preserving ambient isotopy, the unknot Ξ_M, which is characterized by its image being the boundary of an embedded 3–dimensional disk. The surface $\Sigma_M = \Sigma_{\Xi_M}$ associated with Ξ_M is so equipped with a trivializing S–marking preserving homotopy $K_M : \Sigma_M \Rrightarrow I_{\iota_{p_M}}$. For an S–surface knot Ξ, the surface $\Sigma^\sharp{}_\Xi$ measuring its non triviality is thus homotopy equivalent to ${I_{\iota_{p_M}}}^{-1\bullet} \bullet \Sigma_\Xi$ through K_M and then to Σ_Ξ by the standard thin homotopy ${I_{\iota_{p_M}}}^{-1\bullet} \bullet \Sigma_\Xi \Rrightarrow \Sigma_\Xi$. For the purpose of an evaluation of the non triviality of Ξ, Σ_Ξ is hence as good as $\Sigma^\sharp{}_\Xi$. For genus $\ell_S > 0$, the above reasoning fails because the homotopy K_M no longer exists in general, as it is topological obstructed. In that case, for a given S–marking of M, the explicit indication of a reference S–surface knot Ξ_M is then an indispensable element of the construction. The surface $\Sigma^\sharp{}_\Xi$ rather than Σ_Ξ then adequately describes the non triviality of Ξ. This is why we shall concentrate on $\Sigma^\sharp{}_\Xi$ in the following.

The encoding the topology of the S–surface knots $\mathit{\Xi}$ in the surfaces ${\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}$ will be natural only if there is a well defined topological prescription that associates with any S–marking of M a reference topologically trivial S–surface knot $\mathit{\Xi}_M$ unique up to S–marking preserving ambient isotopy. As we cannot prove this in general, we shall assume it as a working hypothesis. Many of the results reported below, however, do not hinge on it.

Definition 2.2.34 *For an S–surface knot $\mathit{\Xi}$, let ${\mathit{\Sigma}^\sharp}_{\mathit{\Xi}} : \iota_{p_M} \Rightarrow \iota_{p_M}$ be the surface of M defined by*

$$ {\mathit{\Sigma}^\sharp}_{\mathit{\Xi}} = {\mathit{\Sigma}_M}^{-1\bullet} \bullet \mathit{\Sigma}_{\mathit{\Xi}}, \tag{2.2.37}$$

where $\mathit{\Sigma}_M = \mathit{\Sigma}_{\mathit{\Xi}_M}$.

Since $\mathit{\Sigma}_{\mathit{\Xi}}, \mathit{\Sigma}_M : \iota_{p_M} \Rightarrow \tau_M$, the composition is well defined and has ι_{p_M} as source and target curves. By (2.1.8a)–(2.1.8d), we have

$$ {\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}(x,y) = p_M \qquad \text{for } x < \epsilon, \tag{2.2.38a}$$

$$ {\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}(x,y) = p_M \qquad \text{for } x > 1-\epsilon, \tag{2.2.38b}$$

$$ {\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}(x,y) = p_M \qquad \text{for } y < \epsilon, \tag{2.2.38c}$$

$$ {\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}(x,y) = p_M \qquad \text{for } y > 1-\epsilon \tag{2.2.38d}$$

for the same number ϵ as in (2.2.30), where we used that $\iota_{p_M}(x) = p_M$. In the following, we shall call ${\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}$ the normalized surface associated to $\mathit{\Xi}$ to distinguish it from the unnormalized surface $\mathit{\Sigma}_{\mathit{\Xi}}$.

On account of def. 2.2.23, the characteristic C–knots ${\zeta_{Si}}^*\mathit{\Xi}$ of an S–surface knot $\mathit{\Xi}$ have an obvious description as curves of M.

Definition 2.2.35 *Let $\mathit{\Xi}$ be an S–surface knot of M. Let $\gamma_{{\zeta_{Si}}^*\mathit{\Xi}} : p_M \rightarrow p_M$ be the curves of M defined as*

$$ \gamma_{{\zeta_{Si}}^*\mathit{\Xi}} = \gamma_{Mi}. \tag{2.2.39}$$

The surface $\varSigma^\sharp{}_\varXi$ and the curves $\gamma_{\zeta_{Si}{}^*\varXi}$ associated with an S–surface knot $\varXi$ and its characteristic C–knots $\zeta_{Si}{}^*\varXi$ enjoy several properties of invariance up to (thin) homotopy.

Proposition 2.2.6 *For any S–surface knot $\varXi$ of M, the surface $\varSigma^\sharp{}_\varXi$ is independent from the choice of the compatible curve γ_C of C and surface $\varSigma_S$ of S congruent with it up to thin homotopy.*

Proof. Suppose first that the genus $\ell_S > 0$. Fix an oriented differentiable universal covering $\tilde S$ of S with orientation preserving covering map $\varpi_S : \tilde S \to S$.

Let γ_C be a curve of C compatible with the pointing of C and $\varSigma_S$ be a surface of S compatible with the marking of S congruent with γ_C (cf. def. 2.2.32). Since $\varSigma_S : \mathbb{R}^2 \to S$ is a map with a simply connected domain, there is a lifting map $\tilde\varSigma_S : \mathbb{R}^2 \to \tilde S$ such that $\varpi_S \circ \tilde\varSigma_S = \varSigma_S$ unique up to left composition by orientation preserving deck diffeomorphisms of $\tilde S$. The compatibility of $\varSigma_S$ (cf. def. 2.2.31) implies further that there is an open set $\tilde F_S$ of $\tilde S$ with the following properties. First, $\tilde F_S$ is the interior of a simply connected fundamental domain of the covering $\tilde S$. Second, $\tilde\varSigma_S$ is a map of $\mathbb{R}^2$ onto $\overline{\tilde F}_S$ and $\tilde\varSigma_S\big|_{D_S}$ is an orientation preserving diffeomorphism of D_S onto $\tilde F_S$. Third, $\varpi_S\big|_{\tilde F_S}$ is an orientation preserving diffeomorphism of $\tilde F_S$ onto the image of $\varSigma_S\big|_{D_S}$. The fact that $\varSigma_S$ expresses a surface $\varSigma_S : \iota_{p_S} \Rightarrow \tau_S$ of S implies then that $\tilde\varSigma_S$ expresses similarly a surface $\tilde\varSigma_S : \iota_{\tilde p_S} \Rightarrow \tilde\tau_S$ of $\tilde S$, where $\tilde p_S$ and $\tilde\tau_S$ are respectively a point and a curve of $\tilde S$ such that $\varpi_S(\tilde p_S) = p_S$ and $\varpi_S \circ \tilde\tau_S = \tau_S$. Since $\tilde F_S$ can be considered to be independent from γ_C and $\varSigma_S$ by the deck symmetry, $\tilde p_S$ and the image of $\tilde\tau_S$ also are. $\tilde\tau_S$ itself, instead, is independent from γ_C only up to thin homotopy. Indeed, reasoning as in the proof of prop. 2.2.1, it is found that the curves α_{Sr}, β_{Sr} composing τ_S according to (2.2.29) and consequently τ_S itself are independent from the choice of γ_C only up to thin homotopy. As it is simple to see, also $\tilde\tau_S$ then is.

Modelling S as $\mathbb{A}/G$, $\tilde{S}$ as $\mathbb{A}$ and ϖ_S as the quotient map of $\mathbb{A}/G$, where $\mathbb{A}$ and G are respectively $\mathbb{R}^2$ and a lattice $\varLambda$ of $\mathbb{R}^2$ for $\ell_S = 1$ and the unit disk $\mathbb{D}_2$ and a Fuchsian group $\varGamma$ for $\ell_S \geq 2$, we can think of $\tilde{\varSigma}_S$ as a surjective map $\tilde{\varSigma}_S : \mathbb{R}^2 \to \mathbb{F}_2$ onto a closed set $\mathbb{F}_2$ of $\mathbb{R}^2$ mapping D_S diffeomorphically and orientation preservingly onto $\mathbb{F}_2$. Relatedly, we can think of $\tilde{\tau}_S$ as a surjective map $\tilde{\tau}_S : \mathbb{R} \to \partial\mathbb{F}_2$.

Let γ_{C0}, γ_{C1} be two curves of C compatible with the pointing of C and $\varSigma_{S0}$, $\varSigma_{S1}$ be two surfaces of S compatible with the marking of S congruent with γ_{C0}, γ_{C1}, respectively. Let $\tilde{\varSigma}_{S0}$, $\tilde{\varSigma}_{S1}$ be the surfaces of $\tilde{S}$ lifting respectively $\varSigma_{S0}$, $\varSigma_{S1}$. From the remarks of the previous paragraph, on account of the thin homotopy of $\tilde{\tau}_{S0}$, $\tilde{\tau}_{S1}$, there is a map $\tilde{h} : \mathbb{R}^2 \to \tilde{S}$ satisfying conditions (2.1.5) with $p_0 = \tilde{p}_S$, $p_1 = \tilde{p}_S$ and $\gamma_0 = \tilde{\tau}_{S0}$, $\gamma_1 = \tilde{\tau}_{S1}$ and (2.1.6). Further, there is a map a map $\tilde{H} : \mathbb{R}^3 \to \tilde{S}$ fulfilling conditions (2.1.14) with $p_0 = p_1 = \tilde{p}_S$, $\tilde{H}(x, 0, z) = \tilde{p}_S$, $\tilde{H}(x, 1, z) = \tilde{h}(x, z)$ and $\varSigma_0 = \tilde{\varSigma}_{S0}$, $\varSigma_1 = \tilde{\varSigma}_{S1}$. Since $\operatorname{rank}(d\tilde{h}(x, z)) \leq 1$, conditions (2.1.15a) are also fulfilled. By mere dimensional reasons, condition (2.1.15b) is fulfilled as well. Thus, $\tilde{H}$ is a thin homotopy of $\tilde{\varSigma}_{S0}$, $\tilde{\varSigma}_{S1}$. It follows immediately that $H = \varpi_S \circ \tilde{H} : \mathbb{R}^3 \to S$ is a thin homotopy of $\varSigma_{S0}$, $\varSigma_{S1}$.

As $\varSigma_{S0}$, $\varSigma_{S1}$ are thin homotopic, for any S–surface knot $\varXi$, $\varXi \circ \varSigma_{S0}$, $\varXi \circ \varSigma_{S1}$ also are. In particular, $\varXi_M \circ \varSigma_{S0}$, $\varXi_M \circ \varSigma_{S1}$ are. Thus, both $\varSigma_\varXi$ and $\varSigma_M = \varSigma_{\varXi_M}$ are independent from the choice of $\varSigma_S$ up to thin homotopy. By (2.2.37) and the fact thin homotopy of surfaces is preserved by vertical composition, we conclude that $\varSigma^\sharp{}_\varXi$ is independent from the choice of $\varSigma_S$ up to thin homotopy.

The proof can be extended straightforwardly to the genus $\ell_S = 0$ case as follows, where consistency of the chosen compatible surface $\varSigma_S$ of S with a given compatible curve γ_C of C is no longer an issue. For $\ell_S = 0$, S is the usual differentiable sphere, which be identified with the one point compactification $\mathbb{R}^2 \cup \infty$ of $\mathbb{R}^2$ via the stereographic projection. Given any two surfaces $\varSigma_{S0}$, $\varSigma_{S1}$ of S compatible with the marking of S, we can find a thin homotopy H of $\varSigma_{S0}$,

$\mathit{\Sigma}_{S1}$ relying on the projection We conclude then again that $\mathit{\Sigma}^\sharp{}_{\mathit{\Xi}}$ is independent from the choice of $\mathit{\Sigma}_S$ up to thin homotopy for any S–surface knot $\mathit{\Xi}$. □

Suppose that we are given two choices $\mathit{\Xi}_{M0}$, $\mathit{\Xi}_{M1}$ of the reference S–surface knot. For any S–surface knot $\mathit{\Xi}$, let $\mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|0}$, $\mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|1}$ be the normalized surfaces associated with $\mathit{\Xi}$ according to (2.2.37) with $\mathit{\Xi}_M = \mathit{\Xi}_{M0}, \mathit{\Xi}_{M1}$, respectively.

Proposition 2.2.7 *If the reference S–surface knots $\mathit{\Xi}_{M0}$, $\mathit{\Xi}_{M1}$ are ambient isotopic, then there is a homotopy ${H_M}^\sharp : \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|0} \Rrightarrow \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|1}$ for any S–surface knot $\mathit{\Xi}$.*

Proof. Let F_{Mz}, $z \in \mathbb{R}$, be an S–marking preserving ambient isotopy relating the knots $\mathit{\Xi}_{M0}$, $\mathit{\Xi}_{M1}$. Define a map $H_M : \mathbb{R}^3 \to M$ by

$$H_M(x, y, z) = F_{Mz} \circ \mathit{\Sigma}_{\mathit{\Xi}_{M0}}(x, y). \tag{2.2.40}$$

Using relations (2.2.36) together with (2.2.2), (2.2.20) and (2.2.25), it is readily checked that H_M satisfies the relations (2.1.14) with $p_0 = p_1 = p_M$ and $\mathit{\Sigma}_0 = \mathit{\Sigma}_{\mathit{\Xi}_{M0}}$, $\mathit{\Sigma}_1 = \mathit{\Sigma}_{\mathit{\Xi}_{M1}}$ for some value of ϵ. From (2.2.25a), (2.2.25b) and (2.2.33), it is checked further that $H_M(x, 0, z) = \iota_{p_M}(x)$, $H_M(x, 1, z) = \tau_M(x)$, so that conditions (2.1.15a) are satisfied too. It follows that (2.2.41) defines a homotopy $H_M : \mathit{\Sigma}_{M0} \Rrightarrow \mathit{\Sigma}_{M1}$, where $\mathit{\Sigma}_{M0} = \mathit{\Sigma}_{\mathit{\Xi}_{M0}}$, $\mathit{\Sigma}_{M1} = \mathit{\Sigma}_{\mathit{\Xi}_{M1}}$. Given an S–surface knot $\mathit{\Xi}$, this induces a homotopy ${H_M}^\sharp : \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|0} \Rrightarrow \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}|1}$ on account of (2.2.37). □

The normalized surfaces of ambient isotopic S–surface knots are homotopic.

Proposition 2.2.8 *If two S–surface knots $\mathit{\Xi}_0$, $\mathit{\Xi}_1$ of M are ambient isotopic, then there exists a homotopy $H^\sharp : \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}_0} \Rrightarrow \mathit{\Sigma}^\sharp{}_{\mathit{\Xi}_1}$.*

Proof. Let F_z, $z \in \mathbb{R}$, be an S–marking preserving ambient isotopy relating the knots $\mathit{\Xi}_0$, $\mathit{\Xi}_1$. Define a map $H : \mathbb{R}^3 \to M$ by

$$H(x, y, z) = F_z \circ \mathit{\Sigma}_{\mathit{\Xi}_0}(x, y). \tag{2.2.41}$$

Reasoning in the same way as in the proof of prop. 2.2.7, one finds that (2.2.41) defines a homotopy $H : \varSigma_{\varXi_0} \Rrightarrow \varSigma_{\varXi_1}$. This induces a homotopy $H^\sharp : \varSigma^\sharp{}_{\varXi_0} \Rrightarrow \varSigma^\sharp{}_{\varXi_1}$ on account of (2.2.37). The statement is so shown. $\square$

As a consequence, the surface $\varSigma^\sharp{}_{\varXi}$ depends only on the ambient isotopy class of the knot $\varXi$ up to homotopy and the map $\varXi \to \varSigma^\sharp{}_{\varXi}$ descends to one from $\mathrm{Knot}_S(M)$ to the set of surfaces of M mod homotopy.

We consider now the curves $\gamma_{\zeta_{Si}{}^*\varXi}$ associated with the characteristic C–knots $\zeta_{Si}{}^*\varXi$ of an S–surface knot $\varXi$.

Proposition 2.2.9 *For any S–surface knot $\varXi$ of M, the curves $\gamma_{\zeta_{Si}{}^*\varXi}$ are independent from the choice of the compatible curve γ_C up to thin homotopy.*

See def 2.2.13, eq. (2.2.10).

Proof. The proof is essentially identical to that of prop. 2.2.1. $\square$

The following proposition is an important though obvious remark.

Proposition 2.2.10 *If two S–surface knots $\varXi_0$, $\varXi_1$ of M are ambient isotopic, then $\gamma_{\zeta_{Si}{}^*\varXi_1} = \gamma_{\zeta_{Si}{}^*\varXi_0}$*

Proof. This follows trivially from (2.2.39). $\square$

Until now, we have considered S–surface knots belonging to a fixed S–marking of M. Analogously to C–knots, in topological applications it is necessary to compare S–surface knots belonging to possibly distinct S–markings. Again, these knots will be topologically equivalent if they are ambient isotopic. Since S–marking preservation is now necessarily broken, the form of ambient isotopy involved here is more general than the one considered earlier. We call it free in keeping with ordinary knot terminology. Prop. 2.2.8 extends also to freely ambient isotopic S–surface knots in a form which we shall make precise next.

When several S–markings $\{p_{M0}, \zeta_{M0i}\}$, $\{p_{M1}, \zeta_{M1i}\}$, $\dots$ of M are given, we shall denote the S–marked manifold M by M_0, M_1, $\dots$ and shall call the S–

surface knots $\varXi$ of M as S–surface knots of M_0, M_1, …, respectively.

Suppose that two possibly distinct S–markings $\{p_{M0}, \zeta_{M0i}\}$, $\{p_{M1}, \zeta_{M1i}\}$ of M are given.

Definition 2.2.36 *Two S–surface knots $\varXi_0$, $\varXi_1$ of M_0, M_1, respectively, are called freely ambient isotopic if they are related by an ambient isotopy W.*

As for C–knots, when the markings are equal, free ambient isotopy does not reduce to ambient isotopy, since S–marking preservation is not required.

We consider now two S–surface knots $\varXi_0$, $\varXi_1$ of M_0, M_1, respectively, which are freely ambient isotopic. If W is the underlying connecting ambient isotopy, $\varXi_0$, $\varXi_1$ are then related as

$$\varXi_1 = W_1 \circ \varXi_0. \tag{2.2.42}$$

In virtue of (2.2.26), $\{p_{M0}, \zeta_{M0i}\}$, $\{p_{M1}, \zeta_{M1i}\}$ are connected accordingly,

$$p_{M1} = W_1(p_{M0}), \tag{2.2.43a}$$

$$\zeta_{M1i} = W_1 \circ \zeta_{M0i}. \tag{2.2.43b}$$

These relations suggest using the isotopy W to construct a smooth family $\{p_{Mz}$, $\zeta_{Mzi}\}$ of S–markings interpolating $\{p_{M0}, \zeta_{M0i}\}$, $\{p_{M1}, \zeta_{M1i}\}$ and a smooth family $\varXi_z$ of S–surface knots of M_z interpolating $\varXi_0$, $\varXi_1$. To this end, we pick again a non decreasing smooth function $\alpha : \mathbb{R} \to [0, 1]$ with the property that $\alpha(u) = 0$ for $u < \epsilon$ and $\alpha(u) = 1$ for $u > 1 - \epsilon$, where $0 < \epsilon < 1/2$ such that the (2.2.9) and (2.2.30) simultaneously hold.

Definition 2.2.37 *For $z \in \mathbb{R}$, let $\{p_{Mz}, \zeta_{Mzi}\}$ be the S–marking of M given by*

$$p_{Mz} = W_{\alpha(z)}(p_{M0}), \tag{2.2.44a}$$

$$\zeta_{Mzi} = W_{\alpha(z)} \circ \zeta_{M0i}. \tag{2.2.44b}$$

We note that $p_{Mz} = p_{M0}$, $\zeta_{Mzi} = \zeta_{M0i}$ for $z < \epsilon$ and $p_{Mz} = p_{M1}$, $\zeta_{Mzi} = \zeta_{M1i}$ for $z > 1 - \epsilon$, where $\{p_{M0}, \zeta_{M0i}\}$ and $\{p_{M1}, \zeta_{M1i}\}$ are the two given S–markings.

Definition 2.2.38 *For $z \in \mathbb{R}$, let $\varXi_z$ be the S–surface knot of M_z given by*

$$\varXi_z = W_{\alpha(z)} \circ \varXi_0. \tag{2.2.45}$$

Properties (2.2.26) are immediately checked. We note that $\varXi_z = \varXi_0$ for $z < \epsilon$ and $\varXi_z = \varXi_1$ for $z > 1 - \epsilon$, where $\varXi_0$ and $\varXi_1$ stand for the given surface knots.

On account of def. 2.2.23 and (2.2.43b), the characteristic C–knots ${\zeta_{Si}}^* \varXi_0$, ${\zeta_{Si}}^* \varXi_1$ of $\varXi_0$, $\varXi_1$ are related as

$${\zeta_{Si}}^* \varXi_1 = W_1 \circ {\zeta_{Si}}^* \varXi_0. \tag{2.2.46}$$

Furthermore, by (2.2.44b), the characteristic C–knots ${\zeta_{Si}}^* \varXi_z$ of $\varXi_z$ smoothly interpolate between ${\zeta_{Si}}^* \varXi_0$, ${\zeta_{Si}}^* \varXi_1$,

$${\zeta_{Si}}^* \varXi_z = W_{\alpha(z)} \circ {\zeta_{Si}}^* \varXi_0. \tag{2.2.47}$$

Clearly, ${\zeta_{Si}}^* \varXi_z = {\zeta_{Si}}^* \varXi_0$ for $z < \epsilon$ and ${\zeta_{Si}}^* \varXi_z = {\zeta_{Si}}^* \varXi_1$ for $z > 1 - \epsilon$, ${\zeta_{Si}}^* \varXi_0$, ${\zeta_{Si}}^* \varXi_1$ being precisely the characteristic C–knots of $\varXi_0$, $\varXi_1$.

In view of (2.2.37), the comparison of the normalized surfaces ${\varSigma^\sharp}_{\varXi_0}$, ${\varSigma^\sharp}_{\varXi_1}$ of two S–surface knots $\varXi_0$, $\varXi_1$ of M_0, M_1, respectively, which are freely ambient isotopic is meaningful only provided the underlying reference S–surface knots $\varXi_{M0}$, $\varXi_{M1}$ of M_0, M_1 are also freely ambient isotopic and the ambient isotopy of $\varXi_0$, $\varXi_1$ is suitably compatible with that of $\varXi_{M0}$, $\varXi_{M1}$.

To the above end, the notion of concordance is apt.

Definition 2.2.39 *Let X be a manifold S–marked by $\{p_X, \zeta_{Xi}\}$. Two smooth families F_z, G_z, $z \in \mathbb{R}$, of autodiffeomorphisms of X are called concordant on the S–marking if $F_z(p_X) = G_z(p_X)$ and $F_z \circ \zeta_{Xi} = G_z \circ \zeta_{Xi}$ for all z.*

For genus $l_S > 0$, the condition of concordance on p_X actually follows from that on the ζ_{Xi} upon evaluation at p_C. We assume now that the reference S–surface knots Ξ_{M0}, Ξ_{M1} are freely ambient isotopic and that the S–surface knots Ξ_0, Ξ_1 are freely ambient isotopic with the underlying isotopy concordant with that of Ξ_{M0}, Ξ_{M1} on $\{p_{M0}, \zeta_{M0i}\}$. Stated explicitly, Ξ_{M0}, Ξ_{M1} are related by an ambient isotopy W_M and Ξ_0, Ξ_1 are related by an ambient isotopy W such that $W_z(p_{M0}) = W_{Mz}(p_{M0})$ and $W_z \circ \zeta_{M0i} = W_{Mz} \circ \zeta_{M0i}$ for all z. In this way, for each z, the interpolating S–markings $\{p_{Mz}, \zeta_{Mzi}\}$ of M constructed according to (2.2.44) are the same for W_M and W. Moreover, the reference surface knots Ξ_{Mz} interpolating Ξ_{M0}, Ξ_{M1} and the surface knots Ξ_z interpolating Ξ_0, Ξ_1 built via (2.2.45) using W_M and W, respectively, are both S–surface knots of M_z. Out of Ξ_{Mz}, Ξ_z, using (2.2.35) and (2.2.37), we can then build a smooth family of normalized surfaces ${\Sigma^\sharp}_{\Xi_z}$ interpolating ${\Sigma^\sharp}_{\Xi_0}$, ${\Sigma^\sharp}_{\Xi_1}$.

Using the interpolating setup constructed above, one can prove the following proposition.

Proposition 2.2.11 *Assume that the reference S–surface knots Ξ_{M0}, Ξ_{M1} of M_0. M_1, respectively, are freely ambient isotopic. Let Ξ_0, Ξ_1 be S–surface knots of M_0. M_1, respectively. Assume that Ξ_0, Ξ_1 are freely ambient isotopic through an isotopy concordant with that of Ξ_{M0}, Ξ_{M1} on $\{p_{M0}, \zeta_{M0i}\}$. Then, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and a homotopy $H : {\Sigma^\sharp}_{\Xi_0} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ {\Sigma^\sharp}_{\Xi_1} \circ I_{\gamma_1}$.*

Here and below, the "compose the rightmost first" convention is extended to multiple horizontal composition of surfaces.

Proof. As z varies, the point p_{Mz} traces a differentiable curve in M. Since p_{Mz} is by itself a C pointing, this is described by the family of curves $\gamma_z : p_{M0} \to p_{Mz}$ defined by (2.2.17) and enjoying the same properties. The ambient isotopies W_z, W_{Mz} connecting Ξ_0 to Ξ_1 and Ξ_{M0} to Ξ_{M1}, respectively, can be employed indifferently in (2.2.17), as these are concordant on $\{p_{M0}, \zeta_{M0i}\}$ by assumption.

With the S–surface knot $\varXi_z$, there is associated the surface ${\varSigma^\sharp}_{\varXi_z}$ according to (2.2.37). By successively composing the curves $\gamma_z : p_{M0} \to p_{Mz}$, $\iota_{p_{Mz}}, : p_{Mz} \to p_{Mz}$ and ${\gamma_z}^{-1\circ} : p_{Mz} \to p_{M0}$, we obtain a curve $\widehat{\iota}_{p_{Mz}} : p_{M0} \to p_{M0}$,

$$\widehat{\iota}_{p_{Mz}} = {\gamma_z}^{-1\circ} \circ \iota_{p_{Mz}} \circ \gamma_z. \tag{2.2.48}$$

By successively horizontally composing the surfaces $I_{\gamma_z} : \gamma_z \Rightarrow \gamma_z$, ${\varSigma^\sharp}_{\varXi_z} : \iota_{p_{Mz}} \Rightarrow \iota_{p_{Mz}}$ and ${I_{\gamma_z}}^{-1\circ} : {\gamma_z}^{-1\circ} \Rightarrow {\gamma_z}^{-1\circ}$, we obtain then a surface ${\widehat{\varSigma}^\sharp}_{\varXi_z} : \widehat{\iota}_{p_{Mz}} \Rightarrow \widehat{\iota}_{p_{Mz}}$,

$${\widehat{\varSigma}^\sharp}_{\varXi_z} = {I_{\gamma_z}}^{-1\circ} \circ {\varSigma^\sharp}_{\varXi_z} \circ I_{\gamma_z}. \tag{2.2.49}$$

For continuously varying z, the surface ${\widehat{\varSigma}^\sharp}_{\varXi_z}$ shifts from the surface ${\widehat{\varSigma}^\sharp}_{\varXi_0}$ to that ${\widehat{\varSigma}^\sharp}_{\varXi_1}$ yielding a homotopy $\widehat{H} : {\widehat{\varSigma}^\sharp}_{\varXi_0} \Rrightarrow {\widehat{\varSigma}^\sharp}_{\varXi_1}$. Indeed, viewed as a map $\widehat{H} : \mathbb{R}^3 \to M$, $\widehat{H}$ is given by

$$\widehat{H}(x, y, z) = {\widehat{\varSigma}^\sharp}_{\varXi_z}(x, y). \tag{2.2.50}$$

By the properties of the curves $\iota_{p_{Mz}}$ and γ_z and the surfaces $\varSigma_{\varXi_z}$, $\varSigma_{Mz}$ and (2.2.50), it is evident that $\widehat{H}$ is smooth. It is readily verified that $\widehat{H}$ satisfies the (2.1.14) with $p_0 = p_1 = p_{M0}$, $\varSigma_0 = {\widehat{\varSigma}^\sharp}_{\varXi_0}$, $\varSigma_1 = {\widehat{\varSigma}^\sharp}_{\varXi_1}$ and perhaps a different value of ϵ. We notice next that $\widehat{H}(x, 0, z) = \widehat{H}(x, 1, z) = \widehat{\iota}_{p_{Mz}}(x)$. Here, $\widehat{\iota}_{p_{Mz}}$ is given by the composition (2.2.48), whose factors γ_z, $\iota_{p_{Mz}}$ have the property that $d_x\gamma_z(x)$, $d_z\gamma_z(x)$ are mutually proportional, by (2.2.17), and that $d_x\iota_{p_{Mz}}(x) = 0$, by (2.1.2). It follows that (2.1.15a) also holds.

By (2.2.49), the source and target surfaces of $\widehat{H}$ explicitly are ${\widehat{\varSigma}^\sharp}_{\varXi_0} = {I_{\iota_{p_{M0}}}}^{-1\circ} \circ {\varSigma^\sharp}_{\varXi_0} \circ I_{\iota_{p_{M0}}}$ and ${\widehat{\varSigma}^\sharp}_{\varXi_1} = {I_{\gamma_1}}^{-1\circ} \circ {\varSigma^\sharp}_{\varXi_1} \circ I_{\gamma_1}$. Since ${I_{\iota_{p_{M0}}}}^{-1\circ} \circ {\varSigma^\sharp}_{\varXi_0} \circ I_{\iota_{p_{M0}}}$ is thin homotopic to ${\varSigma^\sharp}_{\varXi_0}$, $\widehat{H}$ induces a homotopy $H : {\varSigma^\sharp}_{\varXi_0} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ {\varSigma^\sharp}_{\varXi_1} \circ I_{\gamma_1}$. $\square$

Our last task is the comparison of the curves $\gamma_{\zeta_{Si}{}^*\varXi_0}$, $\gamma_{\zeta_{Si}{}^*\varXi_1}$ of the characteristic C–knots $\zeta_{Si}{}^*\varXi_0$, $\zeta_{Si}{}^*\varXi_1$ of two freely ambient isotopic S–surface knots $\varXi_0$, $\varXi_1$.

Proposition 2.2.12 *Let Ξ_0, Ξ_1 be S–surface knots of M_0, M_1, respectively. Assume further that Ξ_0, Ξ_1 are freely ambient isotopic. Then, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ and $2\ell_S$ homotopies $h_i : \gamma_{\zeta_{Si}{}^*\Xi_0} \Rightarrow {\gamma_1}^{-1_\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1$. Further, γ_1 can be taken to be be the same curve as that indicated in prop. 2.2.11 under the hypotheses of this latter.*

Proof. Fix $i = 1, \ldots, 2\ell_S$. As z varies, the knots ζ_{Mzi} trace $2\ell_S$ differentiable surfaces in M. These are described by the families of curves $\gamma_{Mzi} : p_{Mz} \to p_{Mz}$ associated to the S–markings $\{p_{Mz}, \zeta_{Mzi}\}$ according to (2.2.31). The expected properties are verified: $\gamma_{Mzi} = \gamma_{M0i}$ for $z < \epsilon$, $\gamma_{Mzi} = \gamma_{M1i}$ for $z > 1 - \epsilon$.

With the ambient isotopy W connecting Ξ_0 to Ξ_1, there is attached again the family of curves γ_z defined by expression (2.2.17) as in the proof of prop. 2.2.11. By composing successively the curves $\gamma_z : p_{M0} \to p_{Mz}$, $\gamma_{Mzi} : p_{Mz} \to p_{Mz}$ and ${\gamma_z}^{-1_\circ} : p_{Mz} \to p_{M0}$, we obtain the curves $\widehat{\gamma}_{Mzi} : p_{M0} \to p_{M0}$

$$\widehat{\gamma}_{Mzi} = {\gamma_z}^{-1_\circ} \circ \gamma_{Mzi} \circ \gamma_z \tag{2.2.51}$$

For continuously varying z, the curve $\widehat{\gamma}_{Mzi}$ shifts from the curve $\widehat{\gamma}_{M0i}$ to that $\widehat{\gamma}_{M1i}$ giving a homotopy of these latter. To see this, define $\widehat{h}_i : \mathbb{R}^2 \to M$ by

$$\widehat{h}_i(x, y) = \widehat{\gamma}_{Myi}(x). \tag{2.2.52}$$

By the properties of the curves γ_{Mzi} and γ_z and (2.2.52), it is evident that $\widehat{h}_i$ is smooth and it is readily verified that $\widehat{h}_i$ satisfies the (2.1.5) with $p_0 = p_1 = p_{M0}$, $\gamma_0 = \widehat{\gamma}_{M0i}$, $\gamma_1 = \widehat{\gamma}_{M1i}$ for some value of ϵ. So, (2.2.52) defines a homotopy $\widehat{h}_i : \widehat{\gamma}_{M0i} \Rightarrow \widehat{\gamma}_{M1i}$.

By (2.2.51), the source and target curves of $\widehat{h}_i$ are $\widehat{\gamma}_{M0i} = {\iota_{p_{M0}}}^{-1_\circ} \circ \gamma_{M0i} \circ \iota_{p_{M0}}$ and $\widehat{\gamma}_{M1i} = {\gamma_1}^{-1_\circ} \circ \gamma_{M1i} \circ \gamma_1$. As ${\iota_{p_{M0}}}^{-1_\circ} \circ \gamma_{M0i} \circ \iota_{p_{M0}}$ is thin homotopic γ_{M0i}, the homotopy $\widehat{h}_i$ induces a homotopy $h_i : \gamma_{M0i} \Rightarrow {\gamma_1}^{-1_\circ} \circ \gamma_{M1i} \circ \gamma_1$. Recalling that according to (2.2.39) $\gamma_{\zeta_{Si}{}^*\Xi_z} = \gamma_{Mzi}$, we conclude that the statement holds. $\square$

As a free S–surface knot $\varXi$ is an S–surface knot belonging to the S–marking $\{\varXi(p_S),\zeta_{Si}{}^*\varXi\}$ of M, we can construct the associated normalized surface $\varSigma^\sharp{}_\varXi:\iota_{\varXi(p_S)}\Rightarrow\iota_{\varXi(p_S)}$ and $2\ell_S$ curves $\gamma_{\zeta_{Si}{}^*\varXi}:\varXi(p_S)\rightarrow\varXi(p_S)$ as detailed above. The definition of $\varSigma^\sharp{}_\varXi$ involves a reference S–surface knot of $\{\varXi(p_S),\zeta_{Si}{}^*\varXi\}$.

Definition 2.2.40 *For a free S–surface knot $\varXi$, the reference S–surface knot $\varXi_{M\varXi}$ of the S–marking $\{\varXi(p_S),\zeta_{Si}{}^*\varXi\}$ is said concomitant to $\varXi$.*

Unlike for an S–surface knot $\varXi$, for which the reference S–surface knot $\varXi_M$ is a datum, for a free S–surface knot $\varXi$, the concomitant reference S–surface knot $\varXi_{M\varXi}$ is dependent on $\varXi$. Under our working hypothesis, it is determined by $\varXi$ up to S–marking preserving ambient isotopy.

The surface $\varSigma^\sharp{}_\varXi$ and the curves $\gamma_{\zeta_{Si}{}^*\varXi}$ of a free S–surface knot $\varXi$ depend on the the marking $\{p_S,\zeta_{Si}\}$ of S, which up to now we have tacitly assumed to be fixed, while $\varXi$ as a mere embedding of S into M does not. Of course, there are infinitely many choices of $\{p_S,\zeta_{Si}\}$ and any particular one is merely conventional. To be natural, our construction should be independent from the choice made in a suitable sense. Let us see how.

When several markings $\{p_{S0},\zeta_{S0i}\}$, $\{p_{S1},\zeta_{S1i}\}$, $\ldots$ of S are envisaged, we shall denote S by S_0, S_1, $\ldots$, call a target S–marked manifold M an S_0–, S_1–, $\ldots$ marked manifold and the S–surface knots $\varXi$ it supports S_0–, S_1–, $\ldots$ surface knots, respectively, to indicate which marking of S is referred to.

Assume that two markings $\{p_{S0},\zeta_{S0i}\}$ and $\{p_{S1},\zeta_{S1i}\}$ of S with the same underlying C–pointing p_C are given and that the manifold M is S_0– and S_1– marked by $\{p_{M0},\zeta_{M0i}\}$, $\{p_{M1},\zeta_{M1i}\}$, respectively. Suppose further that $\varXi$ is simultaneously an S_0–surface knot of M_0 and an S_1–surface knot of M_1. The natural question arises about the relation between the normalized surfaces $\varSigma^\sharp{}_{0\varXi}$, $\varSigma^\sharp{}_{1\varXi}$ associated with $\varXi$ in the two markings. Since the definition of such surfaces according to (2.2.37) involves the reference S_0–surface knot $\varXi_{M0}$ of M_0 and S_1–surface knots Ξ_{M1} of M_1, this relation will not be simple unless Ξ_{M0}, Ξ_{M1} themselves are simply related. In what follows, we assume that $\Xi_{M0} = \Xi_{M1} = \Xi_M$ perhaps up to S_0– and S_1–marking preserving ambient isotopy, respectively, where Ξ_M is simultaneously an S_0–surface knot of M_0 and an S_1–surface knot of M_1.

Lemma 2.2.1 *There is an orientation preserving isotopy k_z, $z \in \mathbb{R}$, relating the markings $\{p_{S0}, \zeta_{S0i}\}$ and $\{p_{S1}, \zeta_{S1i}\}$.*

Proof. The markings $\{p_{S0}, \zeta_{S0i}\}$ and $\{p_{S1}, \zeta_{S1i}\}$ of S are homotopically equivalent in the sense of algebraic topology, since both the ζ_{S0i} and the ζ_{S1i} represent the $2\ell_S$ homotopy classes of the standard oriented a– and b–cycles of S. There is thus an orientation preserving isotopy k_z, $z \in \mathbb{R}$, deforming $\{p_{S0}, \zeta_{S0i}\}$ into $\{p_{S1}, \zeta_{S1i}\}$, that is such that $k_1(p_{S0}) = p_{S1}$, $k_1 \circ \zeta_{S0i} = \zeta_{S1i}$. □

We now have the following proposition.

Proposition 2.2.13 *Suppose that the reference S_0–surface knot Ξ_{M0} of M_0 and S_1–surface knot Ξ_{M1} of M_1 are both equal to a simultaneous S_0– and S_1 surface knot Ξ_M of M_0 and M_1 perhaps up to S_0– and S_1–marking preserving ambient isotopy, respectively. Let Ξ be a simultaneous S_0– and S_1–surface knot of M_0 and M_1, respectively, having the following properties: $\Xi \circ k_z(p_{S0}) = \Xi_M \circ k_z(p_{S0})$ and $\Xi \circ k_z \circ \zeta_{S0i} = \Xi_M \circ k_z \circ \zeta_{S0i}$ for all z, where k_z is an orientation preserving isotopy with the properties stated in lemma 2.2.1. Then, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and a thin homotopy $H : \Sigma^\sharp{}_{0\Xi} \Rrightarrow I_{\gamma_1}{}^{-1\circ} \circ \Sigma^\sharp{}_{1\Xi} \circ I_{\gamma_1}$, both with image contained in that of Ξ.*

Proof. Preliminarily, we examine the unnormalized surfaces $\Sigma_{0\Xi}$, $\Sigma_{1\Xi}$ of a simultaneous S_0– and S_1–surface knot Ξ of M_0 and M_1. To construct them, compatible surfaces Σ_{S0}, Σ_{S1} of S_0, S_1, respectively, must be picked. From the proof of prop. 2.2.6, $\Sigma_{0\Xi}$, $\Sigma_{1\Xi}$ are independent from the choice of Σ_{S0}, Σ_{S1} up to thin homotopy. This allows us to enforce a convenient relationship between Σ_{S0}, Σ_{S1}. We select $\varSigma_{S0}$, $\varSigma_{S1}$ related as $\varSigma_{S1} = f \circ \varSigma_{S0}$ with $f = k_1$, where k_z is an orientation preserving isotopy with the properties of lemma 2.2.1.

The composition $\varXi \circ f$ is an S_0–surface of M_1. As $f = k_1$, the composition $\varXi \circ k_z$ defines an isotopy of the S_0–surface knots $\varXi$ and $\varXi \circ f$. By the isotopy extension theorem, there is an ambient isotopy W_z, $z \in \mathbb{R}$, of $\varXi$ and $\varXi \circ f$ with $W_z \circ \varXi = \varXi \circ k_z$. The same holds true for the reference S_0–and S_1–surface knot $\varXi_M$ of M_0 and M_1, with a generally different ambient isotopy W_{Mz}. The S_0–surface knots $\varXi$, $\varXi \circ f$ are thus freely ambient isotopic and similarly $\varXi_M$, $\varXi_M \circ f$.

Because of the assumptions made, we have $W_z(p_{M0}) = W_z \circ \varXi(p_{S0}) = \varXi \circ k_z(p_{S0}) = \varXi_M \circ k_z(p_{S0}) = W_{Mz} \circ \varXi_M(p_{S0}) = W_{Mz}(p_{M0})$ and $W_z \circ \zeta_{M0i} = W_z \circ \varXi \circ \zeta_{S0i} = \varXi \circ k_z \circ \zeta_{S0i} = \varXi_M \circ k_z \circ \zeta_{S0i} = W_{Mz} \circ \varXi_M \circ \zeta_{S0i} = W_{Mz} \circ \zeta_{M0i}$ for all real z. The ambient isotopies W_z, W_{Mz} are therefore concordant on $\{p_{M0}, \zeta_{M0i}\}$ (cf. def. 2.2.39).

By prop. 2.2.11 with $\varXi_{M0} = \varXi_M$, $\varXi_{M1} = \varXi_M \circ f$ and $\varXi_0 = \varXi$, $\varXi_1 = \varXi \circ f$, there is a homotopy $H : {\varSigma^\sharp}_{0\varXi} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ {\varSigma^\sharp}_{0\varXi\circ f} \circ I_{\gamma_1}$, where $\gamma_1 : p_{M0} \rightarrow p_{M1}$ is a curve of M. Now, as $\varSigma_{S1} = f \circ \varSigma_{S0}$, $\varSigma_{1\varXi} = \varSigma_{0\varXi\circ f}$ and $\varSigma_{1\varXi_{M1}} = \varSigma_{0\varXi_{M1}\circ f}$ by (2.2.35). Taking (2.2.37) into account, we find that the above is also a homotopy $H : {\varSigma^\sharp}_{0\varXi} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ {\varSigma^\sharp}_{1\varXi} \circ I_{\gamma_1}$.

As explained in the proof of prop. 2.2.11, the homotopy H is the composition of the standard thin homotopy ${\varSigma^\sharp}_{0\varXi} \Rrightarrow {I_{\iota_{p_{M0}}}}^{-1\circ} \circ {\varSigma^\sharp}_{0\varXi} \circ I_{\iota_{p_{M0}}}$ and the homotopy $\widehat{H} : {I_{\iota_{p_{M0}}}}^{-1\circ} \circ {\varSigma^\sharp}_{0\varXi} \circ I_{\iota_{p_{M0}}} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ {\varSigma^\sharp}_{1\varXi} \circ I_{\gamma_1}$ defined by (2.2.48)–(2.2.50), here with ${\varSigma^\sharp}_{\varXi_z}$ replaced by ${\varSigma^\sharp}_{0\varXi_z}$. The curve γ_z and the surface ${\varSigma^\sharp}_{0\varXi_z}$ entering in (2.2.49) are built from (2.2.45) and its reference analog, (2.2.37) and (2.2.17), with W, W_M the free ambient isotopies introduced above. Since $W_z \circ \varXi = \varXi \circ k_z$, $W_{Mz} \circ \varXi_M = \varXi_M \circ k_y$, we have $\gamma_y(x) = W_{\alpha(x)\alpha(y)}(\varXi(p_{S0})) = \varXi(k_{\alpha(x)\alpha(y)}(p_{S0}))$ and $\varSigma_{0\varXi_z}(x,y) = W_{\alpha(z)}(\varXi(\varSigma_{S0}(x,y))) = \varXi(k_{\alpha(z)}(\varSigma_{S0}(x,y)))$, $\varSigma_{0Mz}(x,y) = W_{M\alpha(z)}(\varXi_M(\varSigma_{S0}(x,y))) = \varXi_M(k_{\alpha(z)}(\varSigma_{S0}(x,y)))$. Hence, the images of γ_z and ${\varSigma^\sharp}_{0\varXi_z}$ are contained in that of $\varXi$. As this latter is a differentiable surface in M, $\widehat{H}$ satisfies (2.1.15b) for dimensional reasons. $\widehat{H}$ is therefore a thin homotopy. It follows that H is a thin homotopy. By the property of the curve γ_y just found, the image of the curve γ_1 as well as the homotopy H are contained in that of the knot ξ. $\square$

The characteristic C–knots ${\zeta_{S0i}}^*\mathit{\Xi}$, ${\zeta_{S1i}}^*\mathit{\Xi}$ of an S_0– and S_1–knot $\mathit{\Xi}$ of M_0 and M_1 depend on which marking one assumes. However, they are independent form the marking up to homotopy.

Proposition 2.2.14 *Let $\mathit{\Xi}$ be a simultaneous S_0– and S_1–surface knot of M_0 and M_1, respectively. Then, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and $2\ell_S$ homotopies $h_i : \gamma_{0{\zeta_{S0i}}^*\mathit{\Xi}} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{1{\zeta_{S1i}}^*\mathit{\Xi}} \circ \gamma_1$ all with image contained in that of $\mathit{\Xi}$. Further, γ_1 can be taken to be the same curve as that indicated in prop. 2.2.13 under the hypotheses of this latter.*

Proof. Let again $f = k_1$, where k_z is the orientation preserving isotopy of lemma 2.2.1. We showed in the proof of prop. 2.2.13 that the S_0–surface knots $\mathit{\Xi}$, $\mathit{\Xi} \circ f$ are freely ambient isotopic with the underlying ambient isotopy W_z satisfying $W_z \circ \mathit{\Xi} = \mathit{\Xi} \circ k_z$. By prop. 2.2.12 with $\mathit{\Xi}_0 = \mathit{\Xi}$, $\mathit{\Xi}_1 = \mathit{\Xi} \circ f$ there is then a homotopy $h_i : \gamma_{0{\zeta_{S0i}}^*\mathit{\Xi}} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{0{\zeta_{S0i}}^*(\mathit{\Xi}\circ f)} \circ \gamma_1$, where the curve $\gamma_1 : p_{M0} \to p_{M1}$ is defined as in the proof of prop. 2.2.13 and has hence the properties shown there. Since $\gamma_{0{\zeta_{S0i}}^*(\mathit{\Xi}\circ f)} = \gamma_{M1i} = \gamma_{1{\zeta_{S1i}}^*\mathit{\Xi}}$ by (2.2.39) trivially, $h_i : \gamma_{0{\zeta_{S0i}}^*\mathit{\Xi}} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{1{\zeta_{S1i}}^*\mathit{\Xi}} \circ \gamma_1$.

The homotopy h_i is the composition of the standard thin homotopy $\gamma_{0{\zeta_{S0i}}^*\mathit{\Xi}} \Rightarrow {\iota_{p_{M0}}}^{-1\circ} \circ \gamma_{0{\zeta_{S0i}}^*\mathit{\Xi}} \circ \iota_{p_{M0}}$ and the homotopy $\widehat{h}_i$ defined in (2.2.52) in terms of the family of curves $\widehat{\gamma}_{Myi}$. $\widehat{\gamma}_{Myi}$ in turn is expressed according to (2.2.51) in terms of γ_y, γ_{Myi}. The image of γ_y lies in that of $\mathit{\Xi}$ as shown in the proof of prop. 2.2.13. Since $\gamma_{Myi} = W_{\alpha(y)} \circ \gamma_{M0i} = W_{\alpha(y)} \circ \mathit{\Xi} \circ \gamma_{S0i} = \mathit{\Xi} \circ k_{\alpha(y)} \circ \gamma_{S0i}$, image of γ_{Myi} is also contained in that of $\mathit{\Xi}$. The same holds thus true also for the image of $\widehat{h}_i$ and consequently h_i. $\square$

2.3 2–knots and source autodiffeomorphism action

In this subsection, we consider the role source autodiffeomorphisms on knots. We begin by reviewing this matter for ordinary knots and the we show how the analysis extends to higher knots.

We let again C be an oriented differentiable closed curve with a choice of pointing (cf. subsect. 2.2). We let further M be a manifold, but we assume no C–pointing in it.

Autodiffeomorphisms of C act on free C–knots by right composition.

Lemma 2.3.1 *Let ξ be a free C–knot and let f be an orientation preserving autodiffeomorphism of C. Then, $\xi \circ f$ is a free C–knot too.*

Proof. The statement is obvious. □

Definition 2.3.1 *For a free C–knot ξ and an orientation preserving autodiffeomorphism f of C, we set*

$$f^*\xi = \xi \circ f. \tag{2.3.1}$$

$f^*\xi$ is called the pull–back of ξ by f.

Free C–knot pull-back is compatible with ambient isotopy.

Proposition 2.3.1 *If ξ_0, ξ_1 are ambient isotopic free C–knots, so are their pull–backs $f^*\xi_0$, $f^*\xi_1$ by any orientation preserving autodiffeomorphism f.*

Proof. Let F be an ambient isotopy relating ξ_0, ξ_1. Then, relation (2.2.4) holds. From (2.3.1), it follows that $f^*\xi_1 = F_1 \circ f^*\xi_0$. Consequently, $f^*\xi_0$, $f^*\xi_1$ are also ambient isotopic. □

We denote by $\mathrm{Diff}(C)$ the group of orientation preserving autodiffeomorphisms of C. It follows that the pull–back action descends to a right action of $\mathrm{Diff}(C)$ on $\mathrm{Knot}_{FC}(M)$, called source autodiffeomorphism action.

The fact that every orientation preserving autodiffeomorphism of C is isotopic to id_C entails that the source autodiffeomorphism action of $\mathrm{Diff}(C)$ on $\mathrm{Knot}_{\mathrm{F}C}(M)$ is completely trivial.

Proposition 2.3.2 *For any free C–knot ξ and any orientation preserving autodiffeomorphism f of C, the free C–knot $f^*\xi$ is ambient isotopic to ξ.*

Proof. Since all orientation preserving autodiffeomorphisms of C are isotopic to id_C, there is an orientation preserving isotopy k_y, $y \in \mathbb{R}$, transforming id_C into f. The composition $\xi \circ k_y$ is then an isotopy of the C–knots ξ, $f^*\xi$, by (2.3.1). By the isotopy extension theorem, there is an ambient isotopy W_y, $y \in \mathbb{R}$ of ξ, $f^*\xi$ such that $W_y \circ \xi = \xi \circ k_y$. □

Next, we shall study the properties of the curve $\gamma_\xi : \xi(p_C) \to \xi(p_C)$ associated with a free C–knot ξ under the source autodiffeomorphism action $\xi \mapsto f^*\xi$. The following proposition is expected from prop. 2.3.2.

Proposition 2.3.3 *Let ξ be a free C–knot and let f be an orientation preserving autodiffeomorphisms of C. Then, there are a curve $\gamma_f : \xi(p_C) \to f^*\xi(p_C)$ of M and a thin homotopy $h_f : \gamma_\xi \Rightarrow {\gamma_f}^{-1\circ} \circ \gamma_{f^*\xi} \circ \gamma_f$, both with image contained in that of ξ.*

In this subsection, we continue to use the "compose the rightmost first" rule for the composition of curves introduced in subsect. 2.2.

Proof. ξ, $f^*\xi$ are C–knots belonging to the C–pointings $\xi(p_C)$, $f^*\xi(p_C)$ of M, respectively. As such, they are freely ambient isotopic by prop. 2.3.2. By prop. 2.2.3 with $p_{M0} = \xi(p_C)$, $p_{M1} = f^*\xi(p_C)$ and $\xi_0 = \xi$ and $\xi_1 = f^*\xi$, there is then a homotopy $h : \gamma_\xi \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{f^*\xi} \circ \gamma_1$, where $\gamma_1 : \xi(p_C) \to f^*\xi(p_C)$ is a curve of M. h is the composition of the standard thin homotopy $\gamma_\xi \Rightarrow {\iota_{\xi(p_C)}}^{-1\circ} \circ \gamma_\xi \circ \iota_{\xi(p_C)}$ and the homotopy $\widehat{h} : {\iota_{\xi(p_C)}}^{-1\circ} \circ \gamma_\xi \circ \iota_{\xi(p_C)} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{f^*\xi} \circ \gamma_1$ defined by (2.2.18), (2.2.19). The curves γ_y and γ_{ξ_y} entering in (2.2.18) are built from (2.2.16), (2.2.17), where

W is the free ambient isotopy of ξ, $f^*\xi$ satisfying $W_y \circ \xi = \xi \circ k_y$, as shown in the proof of prop. 2.3.2. Reasoning as in the proof of prop. 2.2.4, one shows that the images of γ_y and γ_{ξ_y} are contained in that of ξ, which is a differentiable curve, so that $\widehat{h}$ satisfies (2.1.6) for dimensional reasons. $\widehat{h}$ is therefore a thin homotopy. It follows that h is a thin homotopy. By the above property of the curves γ_y, γ_{ξ_y}, the images of the curve γ_1 and homotopy h lie in that of the knot ξ. The proposition now follows setting $\gamma_f = \gamma_1$ and $h_f = h$. □

We now switch to surface knot theory. We let again S be an oriented differentiable closed surface with a choice of marking (cf. subsect. 2.2). We let further M be a manifold, but we assume no S–marking in it.

Autodiffeomorphisms of S act on free S–surface knots through right composition.

Lemma 2.3.2 *Let Ξ be a free S–surface knot and let f be an orientation preserving autodiffeomorphism of S. Then, $\Xi \circ f$ is a free S–surface knot too.*

Proof. The statement is obvious. □

Definition 2.3.2 *For a free S–surface knot Ξ and an orientation preserving autodiffeomorphism f of S, we set*

$$f^*\Xi = \Xi \circ f. \tag{2.3.2}$$

$f^*\Xi$ is called the pull–back of Ξ by f.

Free S–surface knot pull-back is compatible with ambient isotopy.

Proposition 2.3.4 *If Ξ_0, Ξ_1 are ambient isotopic free S–surface knots, so are their pull–backs $f^*\Xi_0$, $f^*\Xi_1$ by any orientation preserving autodiffeomorphism f.*

Proof. Let F be an ambient isotopy relating Ξ_0, Ξ_1. Then, relation (2.2.20) holds. From (2.3.2), it follows that $f^*\Xi_1 = F_1 \circ f^*\Xi_0$. Consequently, $f^*\Xi_0$, $f^*\Xi_1$ are also ambient isotopic. □

We denote by $\mathrm{Diff}(S)$ the group of orientation preserving autodiffeomorphisms of S. It follows that the pull–back action descends to a right action of $\mathrm{Diff}(S)$ on $\mathrm{Knot}_{\mathrm{F}S}(M)$, we shall call source autodiffeomorphism action.

Unlike C, not every orientation preserving autodiffeomorphism of S is isotopic to id_C. Prop. 2.3.2, so, extends to surface knots in the following weaker form.

Proposition 2.3.5 *For any free S–surface knot $\varXi$ and any two isotopic orientation preserving autodiffeomorphisms f_0, f_1 of S, the free S–surfaces knots ${f_0}^*\varXi$, ${f_1}^*\varXi$ are ambient isotopic.*

Proof. Since the orientation preserving autodiffeomorphisms f_0, f_1 of S are isotopic, there is an orientation preserving isotopy k_z, $z \in \mathbb{R}$, transforming f_0 into f_1. The composition $\varXi \circ h_z$ is then an isotopy of the S–surface knots ${f_0}^*\varXi$, ${f_1}^*\varXi$, by (2.3.2). By the isotopy extension theorem, there is an ambient isotopy W_z, $z \in \mathbb{R}$ of ${f_0}^*\varXi$ and ${f_1}^*\varXi$ such that $W_z \circ {f_0}^*\varXi = \varXi \circ k_z$. $\square$

Let $\mathrm{Diff}_0(S)$ denote the normal subgroup of $\mathrm{Diff}(S)$ formed by the S–autodiffeomorphisms isotopic to id_S. The classic mapping class group

$$\mathrm{MCG}(S) = \mathrm{Diff}(S)/\,\mathrm{Diff}_0(S) \tag{2.3.3}$$

is then defined. By prop. 2.3.5, the source autodiffeomorphism action of $\mathrm{Diff}(S)$ on $\mathrm{Knot}_{\mathrm{F}S}(M)$ descends to one of $\mathrm{MCG}(S)$ on $\mathrm{Knot}_{\mathrm{F}S}(M)$.

Next, we shall study the properties of the surface ${\varSigma^\sharp}_{\varXi} : \iota_{\varXi(p_S)} \Rightarrow \iota_{\varXi(p_S)}$ associated with a free S–surface knot $\varXi$ under the source autodiffeomorphism action $\varXi \mapsto f^*\varXi$. These properties will not be anything simple, unless the the concomitant reference S–surface knot $\varXi_{M\varXi}$ (cf. def. 2.2.40) behave naturally under the same action. Again, since we cannot prove this in general, we assume it as a working hypothesis. The following couple of propositions are expected from prop. 2.3.5.

Proposition 2.3.6 *Let $\mathit{\Xi}$ be a free S–surface knot and let f_0, f_1 be isotopic orientation preserving autodiffeomorphisms of S. Suppose that the concomitant reference S–surface knots $\mathit{\Xi}_{Mf_0{}^*\mathit{\Xi}}$, $\mathit{\Xi}_{Mf_1{}^*\mathit{\Xi}}$ of $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ are $f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, respectively, where $\mathit{\Xi}_{M\mathit{\Xi}}$ is the concomitant reference S–surface knot of $\mathit{\Xi}$. Suppose further that the free ambient isotopies relating $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ and $f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$ according to prop. 2.3.5 are concordant on the S–marking $\{f_0{}^*\mathit{\Xi}(p_S)$, $\zeta_{Si}{}^*f_0{}^*\mathit{\Xi}\}$ of M. Then, there are a curve $\gamma_{f_0f_1} : f_0{}^*\mathit{\Xi}(p_S) \to f_1{}^*\mathit{\Xi}(p_S)$ of M and a thin homotopy $H_{f_0f_1} : \mathit{\Sigma}^\sharp{}_{f_0{}^*\mathit{\Xi}} \Rrightarrow I_{\gamma_{f_0f_1}}{}^{-1\circ} \circ \mathit{\Sigma}^\sharp{}_{f_1{}^*\mathit{\Xi}} \circ I_{\gamma_{f_0f_1}}$, both with image lying in that of $\mathit{\Xi}$.*

Concordance is defined in 2.2.39. As usual the “compose the rightmost first” rule for the composition of surfaces is used.

Proof. $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ are S–surface knots belonging to the S–markings $\{f_0{}^*\mathit{\Xi}(p_S)$, $\zeta_{Si}{}^*f_0{}^*\mathit{\Xi}\}$, $\{f_1{}^*\mathit{\Xi}(p_S), \zeta_{Si}{}^*f_1{}^*\mathit{\Xi}\}$, respectively. As such, they are freely ambient isotopic by prop. 2.3.5. The concomitant reference S–surface knots $f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$ of $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ are freely ambient isotopic by the same reason. By hypothesis, the ambient isotopy of $f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$ is concordant with that of $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ on the S–marking $\{f_0{}^*\mathit{\Xi}(p_S)$, $\zeta_{Si}{}^*f_0{}^*\mathit{\Xi}\}$ of M. By prop. 2.2.11 using $\{p_{M0}, \zeta_{M0i}\} = \{f_0{}^*\mathit{\Xi}(p_S), \zeta_{Si}{}^*f_0{}^*\mathit{\Xi}\}$, $\{p_{M1}, \zeta_{M1i}\} = \{f_1{}^*\mathit{\Xi}(p_S), \zeta_{Si}{}^*f_1{}^*\mathit{\Xi}\}$ and $\mathit{\Xi}_0 = f_0{}^*\mathit{\Xi}$, $\mathit{\Xi}_1 = f_1{}^*\mathit{\Xi}$, $\mathit{\Xi}_{M0} = f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $\mathit{\Xi}_{M1} = f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, there is a homotopy $H : \mathit{\Sigma}^\sharp{}_{f_0{}^*\mathit{\Xi}} \Rrightarrow I_{\gamma_1}{}^{-1\circ} \circ \mathit{\Sigma}_{f_1{}^*\mathit{\Xi}} \circ I_{\gamma_1}$, where $\gamma_1 : f_0{}^*\mathit{\Xi}(p_S) \to f_1{}^*\mathit{\Xi}(p_S)$ is a curve of M. H is the composition of the standard thin homotopy $\mathit{\Sigma}^\sharp{}_{f_0{}^*\mathit{\Xi}(p_S)} \Rrightarrow I_{\iota_{f_0{}^*\mathit{\Xi}(p_S)}}{}^{-1\circ} \circ \mathit{\Sigma}^\sharp{}_{f_0{}^*\mathit{\Xi}} \circ I_{\iota_{f_0{}^*\mathit{\Xi}(p_S)}}$ and the homotopy $\widehat{H} : I_{\iota_{f_0{}^*\mathit{\Xi}(p_S)}}{}^{-1\circ} \circ \mathit{\Sigma}^\sharp{}_{f_0{}^*\mathit{\Xi}} \circ I_{\iota_{f_0{}^*\mathit{\Xi}(p_S)}} \Rrightarrow I_{\gamma_1}{}^{-1\circ} \circ \mathit{\Sigma}^\sharp{}_{f_1{}^*\mathit{\Xi}} \circ I_{\gamma_1}$ defined by (2.2.48)–(2.2.50). The curve γ_z and the surface $\mathit{\Sigma}^\sharp{}_{\mathit{\Xi}_z}$ entering in (2.2.49) are built from (2.2.17) and (2.2.45) and its reference analog via (2.2.37) with $p_{M0} = f_0{}^*\mathit{\Xi}(p_S)$, $\mathit{\Xi}_0 = f_0{}^*\mathit{\Xi}$, $\mathit{\Xi}_{M0} = f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$ and W, W_M the free ambient isotopies of $f_0{}^*\mathit{\Xi}$, $f_1{}^*\mathit{\Xi}$ and $f_0{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, $f_1{}^*\mathit{\Xi}_{M\mathit{\Xi}}$, respectively, satisfying $W_z \circ \mathit{\Xi} = \mathit{\Xi} \circ h_z$, $W_{Mz} \circ \mathit{\Xi}_{M\mathit{\Xi}} = \mathit{\Xi}_{M\mathit{\Xi}} \circ h_z$ as shown in the proof of prop. 2.3.5. Reasoning as in the proof of prop. 2.2.13, one shows that the images of γ_z, $\varSigma^\sharp{}_{({f_0}^*\varXi)_z}$ are contained in that ${f_0}^*\varXi$ and hence $\varXi$, which is a differentiable surface, so that $\widehat{H}$ satisfies (2.1.15b) by dimensional reasons. $\widehat{H}$ is therefore a thin homotopy. It follows that H is a thin homotopy. By the above property of the curve γ_z and surface $\varSigma^\sharp{}_{({f_0}^*\varXi)_z}$ the images of the curve γ_1 and homotopy H lie in that of the knot $\varXi$. The proposition now follows setting $\gamma_{f_0f_1} = \gamma_1$ and $H_{f_0f_1} = H$. $\square$

Proposition 2.3.7 *Let $\varXi$ be a free S–surface knot and let f_0, f_1 be isotopic orientation preserving autodiffeomorphisms of S. Then, there are a curve $\gamma_{f_0f_1}$: ${f_0}^*\varXi(p_S) \rightarrow {f_1}^*\varXi(p_S)$ of M and $2\ell_S$ homotopies $h_{f_0f_1i} : \gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \Rightarrow {\gamma_{f_0f_1}}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_1}^*\varXi} \circ \gamma_{f_0f_1}$, all with image is contained in that of $\varXi$. Furthermore, $\gamma_{f_0f_1}$ can be taken to be the same curve as in prop. 2.3.6 under the hypotheses of this latter.*

Proof. ${f_0}^*\varXi$, ${f_1}^*\varXi$ are S–surface knots belonging to the S–markings $\{{f_0}^*\varXi(p_S), {\zeta_{Si}}^*{f_0}^*\varXi\}$, $\{{f_1}^*\varXi(p_S), {\zeta_{Si}}^*{f_1}^*\varXi\}$, respectively, which are freely ambient isotopic by prop. 2.3.5. Then, by prop. 2.2.12 with $\{p_{M0}, \zeta_{M0i}\} = \{{f_0}^*\varXi(p_S), {\zeta_{Si}}^*{f_0}^*\varXi\}$, $\{p_{M1}, \zeta_{M1i}\} = \{{f_1}^*\varXi(p_S), {\zeta_{Si}}^*{f_1}^*\varXi\}$ and $\varXi_0 = {f_0}^*\varXi$, $\varXi_1 = {f_1}^*\varXi$, there are a curve $\gamma_1 : {f_0}^*\varXi(p_S) \rightarrow {f_1}^*\varXi(p_S)$ of M and $2\ell_S$ homotopies $h_i : \gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_1}^*\varXi} \circ \gamma_1$. For each i, h_i is the composition of the standard thin homotopy $\gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \Rightarrow {\iota_{{f_0}^*\varXi(p_S)}}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \circ \iota_{{f_0}^*\varXi(p_S)}$ and the homotopy $\widehat{h}_i$: ${\iota_{{f_0}^*\varXi(p_S)}}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \circ \iota_{{f_0}^*\varXi(p_S)} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_1}^*\varXi} \circ \gamma_1$ defined according to (2.2.51), (2.2.52). The curves γ_z and γ_{Mzi} entering in (2.2.51) are built from (2.2.17) and (2.2.47) via (2.2.31) with $p_{M0} = {f_0}^*\varXi(p_S)$, $\varXi_{M0} = {f_0}^*\varXi_{M\varXi}$ and W, the free ambient isotopies of ${f_0}^*\varXi$, ${f_1}^*\varXi$ satisfying $W_z \circ \varXi = \varXi \circ h_z$, as shown in the proof of prop. 2.3.5. Reasoning as in the proof of prop. 2.2.14, one shows that the images of γ_z and γ_{Mzi} are contained in that ${f_0}^*\varXi$ and hence $\varXi$. The same thus holds for the images of γ_1 and the h_i. The proposition now follows setting $\gamma_{f_0f_1} = \gamma_1$ and $h_{f_0f_1i} = h_i$. $\square$

2.4 Sample computations

In this subsection, we present a few simple sample computations to illustrate the abstract constructions of the preceding subsections.

To describe knots in terms of curves and surfaces with sitting instant, it is useful to introduce a function $\alpha : \mathbb{R} \to [0,1]$ such that

$$d_x\alpha(x) \geq 0, \tag{2.4.1a}$$

$$\alpha(x) = 0 \quad \text{for } x < \epsilon, \qquad \alpha(x) = 1 \quad \text{for } x > 1 - \epsilon. \tag{2.4.1b}$$

for some number $\epsilon > 0$ with $\epsilon < 1/2$. For instance,

$$\alpha(u) = g_\beta\left(\frac{1-2u}{(u-\epsilon)(1-\epsilon-u)}\right) \tag{2.4.2}$$

for $\epsilon < u < 1-\epsilon$, $\alpha(u) = 0$ for $u \leq \epsilon$ and $\alpha(u) = 1$ for $u \geq 1-\epsilon$, where

$$g_\beta(w) = \frac{1}{\exp(\beta w) + 1} \tag{2.4.3}$$

with $\beta > 0$ is the Fermi–Dirac function.

For ordinary knots, the base manifold is $C = S^1$, the circle. To aid geometrical intuition, it is convenient to view S^1 as an embedded submanifold of $\mathbb{R}^2$ with radius 1. A standard embedding of this kind is

$$s_{S^1}(\vartheta) = (\cos\vartheta, \sin\vartheta), \tag{2.4.4}$$

with $\vartheta \in [0, 2\pi)$. A natural choice of pointing is $p_{S^1} = (1,0)$. A compatible curve $\gamma_{S^1} : \mathbb{R} \to S^1$ is now given by

$$\gamma_{S^1}(x) = s_{S^1}(2\pi\alpha(x)). \tag{2.4.5}$$

For genus 0 surface knots, the base manifolds is $S = S^2$, the usual sphere. To allow for a pictorial representation, we view S^2 as an embedded submanifold of $\mathbb{R}^3$ with radius 1. A standard embedding of this kind is

$$S_{S^2}(\vartheta, \varphi) = (\cos\vartheta\sin\vartheta(1-\cos\varphi), -\sin\vartheta\sin\varphi, 1-\sin^2\vartheta(1-\cos\varphi)), \tag{2.4.6}$$

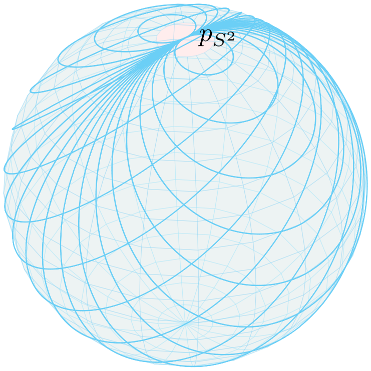

Figure 3: the surface Σ_{S^2}.

where $\vartheta \in (0, \pi)$ and $\varphi \in [0, 2\pi)$. A customary choice of marking of S^2 consists of the point $p_{S^2} = (0, 0, 1)$, the sphere's north pole. A compatible surface $\Sigma_{S^2} : \mathbb{R}^2 \to S^2$ is now given by

$$\Sigma_{S^2}(x, y) = S_{S^2}(\pi\alpha(y), 2\pi\alpha(x)). \tag{2.4.7}$$

In fig. 3, a sequence of constant y curves sweeping S^2 is drawn in cyan [35].

For genus 1 surface knots, $S = T^2$, the familiar torus. For a graphic representation again, we view T^2 as an embedded submanifold of $\mathbb{R}^3$ with toroidal radius 1 and poloidal radius $r < 1$. A standard embedding of this kind is

$$S_{T^2}(\vartheta_1, \vartheta_2) = (\cos\vartheta_1(1 + r\cos\vartheta_2), \sin\vartheta_1(1 + r\cos\vartheta_2), r\sin\vartheta_2), \tag{2.4.8}$$

where $\vartheta_1, \vartheta_2 \in [0, 2\pi)$. A standard marking of T^2 consists of the point $p_{T^2} = (1 + r, 0, 0)$ and the curves

$$\xi_{T^2}(\vartheta) = ((1 + r)\cos\vartheta, (1 + r)\sin\vartheta, 0), \tag{2.4.9a}$$

$$\eta_{T^2}(\vartheta) = (1 + r\cos\vartheta, 0, r\sin\vartheta), \tag{2.4.9b}$$

where $\vartheta \in [0, 2\pi)$. A compatible surface $\Sigma_{T^2} : \mathbb{R}^2 \to T^2$ is given by

$$\Sigma_{T^2}(x, y) = S_{T^2}(2\pi c_1(x, y)), 2\pi c_2(x, y))) \tag{2.4.10}$$

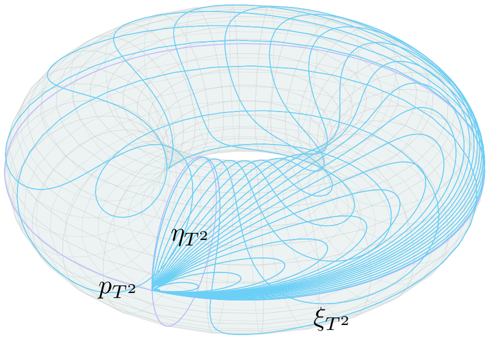

Figure 4: the surface Σ_{T^2}.

where the functions $c_1, c_2 : \mathbb{R}^2 \to [0,1]$ are given by

$$c_1(x,y) = \varrho(4\alpha(x), \alpha(y)) - \varrho(4\alpha(x) - 2, \alpha(y)), \tag{2.4.11a}$$

$$c_2(x,y) = \varrho(4\alpha(x) - 1, \alpha(y)) - \varrho(4\alpha(x) - 3, \alpha(y)), \tag{2.4.11b}$$

$\varrho : \mathbb{R} \times [0,1] \to [0,1]$ is defined by

$$\varrho(s,t) = tg_\beta\left(\frac{1-2s}{(1+s-t)(2-s-t)}\right). \tag{2.4.12}$$

for $t-1 < s < 2-t$, $\varrho(s,t) = 0$ for $s \le t-1$ and $\varrho(s,t) = 1$ for $s \ge 2-t$ and

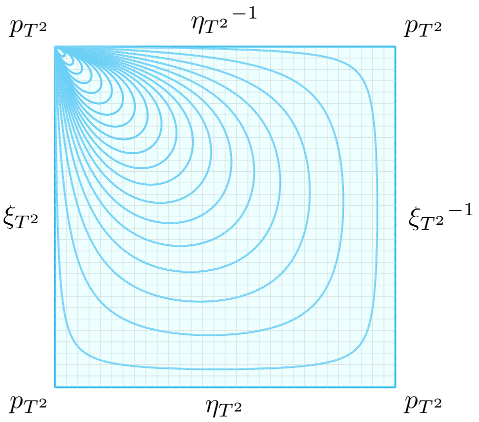

Figure 5: the surface Σ_{T^2} when T^2 is unfolded.

the function g_β is defined in (2.4.3). In fig. 4, a sequence of constant y curves sweeping T^2 are drawn in cyan. In fig. 5, the sequence of curves is shown when the torus is unfolded for a clearer visualization. The curve $\tau_{T^2} : \mathbb{R} \to T^2$ as

$$\tau_{T^2}(x) = S_{T^2}(2\pi c_1(x, y)), 2\pi c_2(x, y))), \tag{2.4.13}$$

where $y > 1 - \epsilon$ whose choice is immaterial.

3 Higher parallel transport and holonomy

In this section, we first review the theory of parallel transport both in ordinary and in strict higher gauge theory. In our presentation, we follow ref. [17], to which the reader is referred to for further details. We then expound our theory of surface holonomy with the main results of this paper.

The relevant algebraic and differential geometric structures on which the following analysis rests are those of Lie group, Lie algebra, Lie crossed module and differential Lie crossed module. These are reviewed in some detail in the appendix of ref. [16], whose notational conventions we adopt. We now recall briefly these notions and their mail properties for the sake of completeness and to the reader's benefit. Below, unless otherwise stated, we work in the category of smooth manifolds and maps.

Definition 3.0.1 *A Lie crossed module consists of a pair of Lie groups* G*,* H *together with two Lie group morphisms* $t : H \to G$ *and* $m : G \to \mathrm{Aut}(H)$*, where* $\mathrm{Aut}(H)$ *is the automorphism group of* H*, obeying the relations*

$$t(m(a)(A)) = at(A)a^{-1}, \tag{3.0.14a}$$

$$m(t(A))(B) = ABA^{-1} \tag{3.0.14b}$$

with $a \in G$*,* $A, B \in H$*.*

Just as the notion of Lie group and Lie algebra are intimately related, so are those of Lie crossed module and differential Lie crossed module.

Definition 3.0.2 *A differential Lie crossed module consists of a pair of Lie algebras* $\mathfrak{g}$*,* $\mathfrak{h}$ *together with two Lie algebra morphism* $\tau : \mathfrak{h} \to \mathfrak{g}$*. and* $\mu : \mathfrak{g} \to \mathfrak{der}(\mathfrak{h})$*, where* $\mathfrak{der}(\mathfrak{h})$ *is the Lie algebra of derivations of* $\mathfrak{h}$*, obeying the relations*

$$\tau(\mu(x)(X)) = [x, \tau(X)]_{\mathfrak{g}}, \tag{3.0.15a}$$

$$\mu(\tau(X))(Y) = [X,Y]_{\mathfrak{h}} \tag{3.0.15b}$$

with $x \in \mathfrak{g}$, $X, Y \in \mathfrak{h}$.

In the same way as there is a Lie algebra canonically derived from any Lie group, there is a differential Lie crossed module canonically derived from any Lie crossed module.

Proposition 3.0.1 *With each Lie crossed module* (G, H, t, m) *there is associated a differential Lie crossed module* $(\mathfrak{g}, \mathfrak{h}, \dot{t}, \widehat{m})$ *with*

$$\dot{t}(X) = \frac{dt(C(v))}{dv}\Big|_{v=0}, \tag{3.0.16a}$$

$$\widehat{m}(x, X) = \frac{\partial}{\partial u}\Big(\frac{\partial m(c(u))(C(v))}{\partial v}\Big|_{v=0}\Big)\Big|_{u=0} \tag{3.0.16b}$$

for $x \in \mathfrak{g}$, $X \in \mathfrak{h}$, *where* $c(u)$ *is any curve in* G *such that* $c(u)\big|_{u=0} = 1_G$ *and* $dc(u)/du\big|_{u=0} = x$ *and* $C(v)$ *is any curve in* H *such that* $C(v)\big|_{v=0} = 1_H$ *and* $dC(v)/dv\big|_{v=0} = X$.

In this paper, we shall need two more mappings arising in any Lie crossed module defined below.

Definition 3.0.3 *Each Lie crossed module* (G, H, t, m) *is characterized by two canonical mappings* $\dot{m} : G \times \mathfrak{h} \to \mathfrak{h}$ *and* $Q : \mathfrak{g} \times H \to \mathfrak{h}$ *defined by*

$$\dot{m}(a)(X) = \frac{d}{dv}m(a)(C(v))\Big|_{v=0}, \tag{3.0.17a}$$

$$Q(x, A) = \frac{d}{du}m(c(u))(A)A^{-1}\Big|_{u=0} \tag{3.0.17b}$$

for $a \in G$, $X \in \mathfrak{h}$, $x \in \mathfrak{g}$, $A \in H$, *where* $c(u)$ *is a curve in* G *such that* $c(u)\big|_{u=0}$ $= 1_G$ *and* $dc(u)/du\big|_{u=0} = x$ *and* $C(v)$ *is a curve in* H *such that* $C(v)\big|_{v=0} = 1_H$ *and* $dC(v)/dv\big|_{v=0} = X$.

3.1 2–parallel transport

In this subsection, we review the construction of higher parallel transport in strict higher gauge theory. This subject has been analyzed in depth in refs. [19–27]. We follow mainly ref. [28]. This material is not original and is presented mainly to make this paper self–contained and for later reference. For this reason, we give no proof of the basic results.

As an introduction to the topic, we review first parallel transport in ordinary gauge theory. Let M be a manifold and G be a Lie group. The trivial principal G–bundle on M is assumed as differentiable background.

We begin by reviewing the notion of G–connection.

Definition 3.1.1 *A G–connection on M, or simply a G–connection, is a form $\theta \in \Omega^1(M, \mathfrak{g})$. A G–connection θ is said flat if*

$$d\theta + \frac{1}{2}[\theta, \theta] = 0. \tag{3.1.1}$$

We now proceed to the definition of parallel transport on ordinary gauge theory.

Definition 3.1.2 *Let θ be a G–connection on M. For any curve γ of M, the element $F_\theta(\gamma) \in G$ defined by*

$$F_\theta(\gamma) = u(1), \tag{3.1.2}$$

where $u : \mathbb{R} \to G$ is the unique solution of the differential problem

$$d_x u(x) u(x)^{-1} = -\gamma^* \theta_x(x), \qquad u(0) = 1_G, \tag{3.1.3}$$

is called the parallel transport along γ induced by θ.

The basic datum required by the construction of parallel transport is thus a G–connection θ on M, which we fix once and for all.

Parallel transport is compatible with the operations on curves of def. 2.1.2.

Proposition 3.1.1 *For any point p of M,*

$$F_\theta(\iota_p) = 1_G. \tag{3.1.4}$$

For any curve γ of M,

$$F_\theta(\gamma^{-1\circ}) = F_\theta(\gamma)^{-1}. \tag{3.1.5}$$

For any two composable curves γ_1, γ_2 of M,

$$F_\theta(\gamma_2 \circ \gamma_1) = F_\theta(\gamma_2)F_\theta(\gamma_1). \tag{3.1.6}$$

F_θ has the fundamental property of homotopy invariance as detailed by the following proposition.

Proposition 3.1.2 *Let γ_y, $y \in \mathbb{R}$, be a smooth 1–parameter family of curves of M with y independent source and target points such that the mapping $h : \mathbb{R}^2 \to M$ defined by $h(x, y) = \gamma_y(x)$ is a thin homotopy $h : \gamma_0 \Rightarrow \gamma_1$ (cf. def. 2.1.3). Then,*

$$F_\theta(\gamma_1) = F_\theta(\gamma_0). \tag{3.1.7}$$

The same relation holds if θ is flat and h is a homotopy

Parallel transport defines a mapping $F_\theta : \Pi_1 M \to G$ of the set $\Pi_1 M$ of curves of M into the group G. Because of the properties stated by props. 3.1.1, 3.1.2, this mapping descends to a functor $\bar{F}_\theta : (M, P_1 M) \to BG$ from the path groupoid $(M, P_1 M)$ of M into the delooping BG of G. When θ is flat, we have further a functor $\bar{F}^0{}_\theta : (M, P^0{}_1 M) \to BG$ from the fundamental groupoid $(M, P^0{}_1 M)$ of M into BG. This is an important categorical characterization of parallel transport, but it will play no role in the following.

We consider next parallel transport in strict higher gauge theory. Let M be a manifold and (G, H) be a Lie crossed module. The trivial principal (G, H)–2–bundle on M is assumed as differentiable background.

Definition 3.1.3 *A (G,H)–2–connection doublet on M, or simply a (G,H)–connection doublet, is a pair (θ,Υ) of a 1–form $\theta\in\Omega^1(M,\mathfrak{g})$ and a 2–form $\Upsilon\in\Omega^2(M,\mathfrak{h})$ satisfying the zero fake curvature condition*

$$d\theta+\frac{1}{2}[\theta,\theta]-\dot{t}(\Upsilon)=0. \tag{3.1.8}$$

A (G,H)–connection (θ,Υ) is said flat if

$$d\Upsilon+\widehat{m}(\theta,\Upsilon)=0. \tag{3.1.9}$$

Parallel transport in higher gauge theory is defined in analogy to ordinary one as follows.

Definition 3.1.4 *Let (θ,Υ) be a (G,H)–2–connection doublet on M.*

For any curve γ of M, the element $F_\theta(\gamma)\in G$ defined as in 3.1.2 is the 1–parallel transport along γ induced by (θ,Υ).

For any any surface Σ of M the element $F_{\theta,\Upsilon}(\Sigma)\in H$ defined by

$$F_{\theta,\Upsilon}(\Sigma)=E(0,1), \tag{3.1.10}$$

where $E:\mathbb{R}^2\to H$ is the unique solution of the two step differential problem

$$\partial_x u(x,y)u(x,y)^{-1}=-\Sigma^*\theta_x(x,y),\qquad u(1,y)=1_G, \tag{3.1.11a}$$

$$\partial_y v(x,y)v(x,y)^{-1}=-\Sigma^*\theta_y(x,y),\qquad v(x,0)=1_G, \tag{3.1.11b}$$

$$\partial_x(\partial_y E(x,y)E(x,y)^{-1})=-\dot{m}(v(1,y)^{-1}u(x,y)^{-1})(\Sigma^*\Upsilon_{xy}(x,y)) \tag{3.1.11c}$$

$$\text{or}\quad \partial_y(E(x,y)^{-1}\partial_x E(x,y))=-\dot{m}(u(x,0)^{-1}v(x,y)^{-1})(\Sigma^*\Upsilon_{xy}(x,y))$$

$$E(1,y)=E(x,0)=1_H.$$

with $u,v:\mathbb{R}^2\to G$, is called the 2–parallel transport along Σ induced by (θ,Υ).

The two forms of the differential problem (3.1.11c) are equivalent: any solution of one is automatically solution of the other. The basic datum required by the construction of 1– and 2–parallel transport is a (G,H)–connection doublet $(\theta,\varUpsilon)$ on M, which we fix once and for all.

The 2–parallel transport along a surface is simply related to the 1–parallel transport along its source and target curves.

Proposition 3.1.3 *Let γ_0,γ_1 be curves with equal source and target points and $\varSigma:\gamma_0\Rightarrow\gamma_1$ be a surface of M. Then,*

$$F_\theta(\gamma_1)=t(F_{\theta,\varUpsilon}(\varSigma))F_\theta(\gamma_0). \tag{3.1.12}$$

Parallel transport is compatible with the operations on curves and surfaces of def. 2.1.5 analogously to the ordinary case.

Proposition 3.1.4 *For any point p of M,* (3.1.4) *holds. For any curve γ of M,* (3.1.5) *also holds. For any two composable curves γ_1,γ_2 of M,* (3.1.6) *holds too. For any curve γ of M, one has*

$$F_{\theta,\varUpsilon}(I_\gamma)=1_H. \tag{3.1.13}$$

For any surface $\varSigma$ of M, one has

$$F_{\theta,\varUpsilon}(\varSigma^{-1\bullet})=F_{\theta,\varUpsilon}(\varSigma)^{-1}. \tag{3.1.14}$$

For any two vertically composable surfaces $\varSigma_1,\varSigma_2$ of M, one has

$$F_{\theta,\varUpsilon}(\varSigma_2\bullet\varSigma_1)=F_{\theta,\varUpsilon}(\varSigma_2)F_{\theta,\varUpsilon}(\varSigma_1). \tag{3.1.15}$$

For any surface $\varSigma$ of M, one has

$$F_{\theta,\varUpsilon}(\varSigma^{-1\circ})=m(F_\theta(\gamma_0)^{-1})(F_{\theta,\varUpsilon}(\varSigma)^{-1}), \tag{3.1.16}$$

where γ_0 is the source curve of $\varSigma$. For any two horizontally composable surfaces $\varSigma_1,\varSigma_2$ of M, one has

$$F_{\theta,\varUpsilon}(\varSigma_2\circ\varSigma_1)=F_{\theta,\varUpsilon}(\varSigma_2)m(F_\theta(\gamma_2))(F_{\theta,\varUpsilon}(\varSigma_1)), \tag{3.1.17}$$

where γ_2 *is the source curve of* $\varSigma_2$*.*

Analogously to the ordinary case, F_θ and $F_{\theta,\varUpsilon}$ enjoy the property of homotopy invariance as established by the following proposition.

Proposition 3.1.5 *Let* γ_y*,* $y \in \mathbb{R}$*, be a smooth* 1*–parameter family of curves of* M *with* y *independent source and target points such that the mapping* $h : \mathbb{R}^2 \to M$ *defined by* $h(x,y) = \gamma_y(x)$ *is a thin homotopy* $h : \gamma_0 \Rightarrow \gamma_1$ *(cf. def. 2.1.6). Then,* (3.1.7) *holds*

Let γ_{0z}, γ_{1z} *and* $\varSigma_z : \gamma_{0z} \Rightarrow \gamma_{1z}$*,* $z \in \mathbb{R}$*, be respectively two* 1*–parameter families of curves with shared* z *independent source and target points and a* 1*–parameter family of surfaces such that the mapping* $H : \mathbb{R}^3 \to M$ *defined by* $H(x,y,z) = \varSigma_z(x,y)$ *is a thin homotopy* $H : \varSigma_0 \Rrightarrow \varSigma_1$*. Then,*

$$F_\theta(\gamma_{01}) = F_\theta(\gamma_{00}), \tag{3.1.18a}$$

$$F_\theta(\gamma_{11}) = F_\theta(\gamma_{10}), \tag{3.1.18b}$$

$$F_{\theta,\varUpsilon}(\varSigma_1) = F_{\theta,\varUpsilon}(\varSigma_0). \tag{3.1.18c}$$

The same relations hold if $(\theta,\varUpsilon)$ *is flat and* H *is a homotopy.*

1– and 2–parallel transport define mappings $F_\theta : \Pi_1 M \to G$, $F_{\theta,\varUpsilon} : \Pi_2 M \to H$ of the sets $\Pi_1 M$, $\Pi_2 M$ of curves and surfaces of M into the groups G, H, respectively. Because of the properties stated by props. 3.1.4, 3.1.5, these mappings descend to a strict 2–functor $\bar{F}_{\theta,\varUpsilon} : (M, P_1 M, P_2 M) \to B(G,H)$ from the path 2–groupoid $(M, P_1 M, P_2 M)$ of M into the delooping $B(G,H)$ of the Lie crossed module (G,H) seen as a strict 2–group. When $(\theta,\varUpsilon)$ is flat, we have further a strict 2–functor $\bar{F}^0{}_{\theta,\varUpsilon} : (M, P_1 M, P^0{}_2 M) \to B(G,H)$ from the fundamental 2–groupoid $(M, P_1 M, P^0{}_2 M)$ of M into $B(G,H)$. Again, this is an important categorical characterization of higher parallel transport, but it will have little import in the following.

3.2 2–parallel transport and 1– and 2–gauge transformation

In this subsection, we review gauge transformation of higher parallel transport in strict higher gauge theory for self–containedness and later reference. Again the material is not original and no proofs are provided [19–27]. We follow mainly ref. [28].

We begin by reviewing gauge transformation of parallel transport in ordinary gauge theory. Let M be a manifold and G be a Lie group. As before, we assume the trivial principal G bundle on M as differentiable background.

Definition 3.2.1 *A G–gauge transformation is a map $g \in \mathrm{Map}(M, G)$.*

G–gauge transformations act on G–connections (cf. def. 3.1.1).

Definition 3.2.2 *Let θ be a G–connection and g be a G–gauge transformation. The gauge transformed G–connection ${}^g\theta$ is*

$$ {}^g\theta = \mathrm{Ad}\, g(\theta) - dgg^{-1}. \tag{3.2.1}$$

Gauge transformations preserves flatness of connections.

Proposition 3.2.1 *If θ is a flat G–connection, then, for any G–gauge transformation g, ${}^g\theta$ is also a flat G–connection (cf. def. 3.1.1).*

Let us now fix a G–connection θ and a G–gauge transformation g. The following proposition is a classic result.

Proposition 3.2.2 *For any curve $\gamma : p_0 \to p_1$ of M, the parallel transports $F_\theta(\gamma)$ and $F_{{}^g\theta}(\gamma)$ along γ are related as*

$$ F_{{}^g\theta}(\gamma) = g(p_1)F_\theta(\gamma)g(p_0)^{-1}. \tag{3.2.2}$$

From a categorical perspective, it can be shown that a G–gauge transformation

g encodes a natural transformation $\bar{F}_\theta \Rightarrow \bar{F}_{g\theta}$ of parallel transport functors (cf. subsect. 3). Furthermore, when θ is flat, g yields a natural transformation $\bar{F}^0{}_\theta \Rightarrow \bar{F}^0{}_{g\theta}$ of flat parallel transport functors.

We now shift to higher gauge theory and review gauge transformation of higher parallel transport. Let M be a manifold and (G,H) be a Lie crossed module. We assume again the trivial principal (G,H)–bundle on M as differentiable background.

Definition 3.2.3 *A (G,H)–1–gauge transformation is a pair (g,J) of a map $g \in \mathrm{Map}(M,G)$ and a 1–form $J \in \Omega^1(M,\mathfrak{h})$.*

(G,H)–1–gauge transformations act on (G,H)–2–connection doublets (cf. def. 3.1.3).

Definition 3.2.4 *Let $(\theta,\varUpsilon)$ be a (G,H)–2–connection doublet and (g,J) be a $(G,\ H)$–1–gauge transformation. The gauge transformed (G,H)–2–connection doublet $({}^{g,J}\theta, {}^{g,J}\varUpsilon)$ is*

$$ {}^{g,J}\theta = \mathrm{Ad}\, g(\theta) - dgg^{-1} - \dot{t}(J), \tag{3.2.3a}$$

$$ {}^{g,J}\varUpsilon = \dot{m}(g)(\varUpsilon) - dJ - \frac{1}{2}[J,J] - \widehat{m}(\mathrm{Ad}\, g(\theta) - dgg^{-1} - \dot{t}(J), J). \tag{3.2.3b}$$

It can be checked that this gauge transformation is compatible with the zero fake curvature condition (3.1.8). It also preserves flatness of connection doublets.

Proposition 3.2.3 *If $(\theta,\varUpsilon)$ is a flat (G,H)–2–connection doublet, then, for every (G,H)–1–gauge transformation (g,J), $({}^{g,J}\theta, {}^{g,J}\varUpsilon)$ is also a flat (G,H)–2–connection doublet (cf. def. 3.1.3).*

The 1–gauge transformation of 1– and 2–parallel transport is more involved than its ordinary counterpart. Let us now fix a (G,H)–2–connection doublet $(\theta,\varUpsilon)$ and a (G,H)–1–gauge transformation (g,J).

Definition 3.2.5 *For any curve γ of M, the element $G_{g,J;\theta}(\gamma) \in H$ defined by*

$$G_{g,J;\theta}(\gamma) = \mathit{\Lambda}(0), \tag{3.2.4}$$

where $\mathit{\Lambda} : \mathbb{R} \to H$ is the unique solution of the differential problem

$$\mathit{\Lambda}(x)^{-1} d_x \mathit{\Lambda}(x) = -\dot{m}(u(x)^{-1}\gamma^* g(x)^{-1})(\gamma^* J_x(x)), \qquad \mathit{\Lambda}(1) = 1_H, \tag{3.2.5}$$

with $u(x)$ being the solution of the differential problem (3.1.3) *but with initial condition $u(1) = 1_G$, is called* 1*–gauge parallel transport along γ.*

The following proposition generalizes prop. 3.2.2.

Proposition 3.2.4 *For any curve $\gamma : p_0 \to p_1$ of M, one has*

$$F_{{}^{g,J}\theta}(\gamma) = g(p_1) t(G_{g,J;\theta}(\gamma)) F_\theta(\gamma) g(p_0)^{-1}. \tag{3.2.6}$$

For any two curves $\gamma_0, \gamma_1 : p_0 \to p_1$ and surface $\mathit{\Sigma} : \gamma_0 \Rightarrow \gamma_1$ of M, one has

$$F_{{}^{g,J}\theta, {}^{g,J}\Upsilon}(\mathit{\Sigma}) = m(g(p_1))\big(G_{g,J;\theta}(\gamma_1) F_{\theta,\Upsilon}(\mathit{\Sigma}) G_{g,J;\theta}(\gamma_0)^{-1}\big). \tag{3.2.7}$$

1–gauge parallel transport is compatible with the curve operations of def. 2.1.5.

Proposition 3.2.5 *For any point p of M, one has*

$$G_{g,J;\theta}(\iota_p) = 1_H. \tag{3.2.8}$$

For any curve γ of M, one has

$$G_{g,J;\theta}(\gamma^{-1\circ}) = m(F_\theta(\gamma)^{-1})(G_{g,J;\theta}(\gamma)^{-1}). \tag{3.2.9}$$

For any two composable curves γ_1, γ_2 of M, one has

$$G_{g,J;\theta}(\gamma_2 \circ \gamma_1) = G_{g,J;\theta}(\gamma_2) m(F_\theta(\gamma_2))(G_{g,J;\theta}(\gamma_1)). \tag{3.2.10}$$

1–gauge parallel transport is thin homotopy invariant.

Proposition 3.2.6 *Let γ_y, $y \in \mathbb{R}$, be a smooth 1–parameter family of curves with y independent source and target points such that the mapping $h : \mathbb{R}^2 \to M$ defined by $h(x, y) = \gamma_y(x)$ is a thin homotopy of γ_0, γ_1. Then,*

$$G_{g,J;\theta}(\gamma_1) = G_{g,J;\theta}(\gamma_0). \tag{3.2.11}$$

By prop. 3.2.6, the map $G_{g;J;\theta} : \Pi_1 M \to H$ of the set $\Pi_1 M$ of curves of M into the group H induces one $\bar{G}_{g;J;\theta} : P_1 M \to H$ of the set $P_1 M$ of thin homotopy classes of curves of M into H. From a categorical perspective, props. 3.2.4 and 3.2.5 entail that a (G, H)–1–gauge transformation (g, J) encodes a pseudonatural transformation $\bar{G}_{g,J;\theta} : \bar{F}_{\theta,\mathit{\Upsilon}} \Rightarrow \bar{F}_{{}^{g,J}\theta,{}^{g,J}\mathit{\Upsilon}}$ of parallel transport 2–functors. If $(\theta, \mathit{\Upsilon})$ is flat, then (g, J) yields a pseudonatural transformation $\bar{G}^0{}_{g,J;\theta} : \bar{F}^0{}_{\theta,\mathit{\Upsilon}} \Rightarrow \bar{F}^0{}_{{}^{g,J}\theta,{}^{g,J}\mathit{\Upsilon}}$ of flat parallel transport 2–functors.

Higher gauge theory enjoys also gauge for gauge symmetry. This plays no role in the theory of surface knot invariants. We touch it briefly only for the sake of completeness.

Definition 3.2.6 *A (G, H)–2–gauge transformation is a map $\mathit{\Omega} \in \mathrm{Map}(M, H)$.*

(G, H)–2–gauge transformations act on (G, H)–1–gauge transformations, the action depending on an assigned (G, H)–2–connection doublet.

Definition 3.2.7 *Let $(\theta, \mathit{\Upsilon})$ be a (G, H)–2–connection doublet, (g, J) be a (G, H)–1–gauge transformation and $\mathit{\Omega}$ a (G, H)–2–gauge transformation. The 2–gauge transformed 1–gauge transformation $({}^{\mathit{\Omega}}g_{|\theta}, {}^{\mathit{\Omega}}J_{|\theta})$ is given by*

$${}^{\mathit{\Omega}}g_{|\theta} = t(\mathit{\Omega})g, \tag{3.2.12a}$$

$${}^{\mathit{\Omega}}J_{|\theta} = \mathrm{Ad}\,\mathit{\Omega}(J) - d\mathit{\Omega}\mathit{\Omega}^{-1} - Q({}^{g,J}\theta, \mathit{\Omega}). \tag{3.2.12b}$$

where ${}^{g,J}\theta$ is given in (3.2.3a)*.*

Let us now fix a (G, H)–connection doublet $(\theta, \mathit{\Upsilon})$ and a (G, H)–1–gauge transformation (g,J). 2–gauge equivalent 1–gauge transformations yield the the same gauge transformed connection doublet.

Proposition 3.2.7 *Let Ω be a (G,H)–2–gauge transformation. Then,*

$${}^{{}^{\Omega}g_{|\theta},{}^{\Omega}J_{|\theta}}\theta = {}^{g,J}\theta, \tag{3.2.13a}$$

$${}^{{}^{\Omega}g_{|\theta},{}^{\Omega}J_{|\theta}}\Upsilon = {}^{g,J}\Upsilon. \tag{3.2.13b}$$

The action of 2–gauge transformations on 1–gauge transformations translates into one on the map $\gamma \rightarrow G_{g,J;\theta}(\gamma)$.

Proposition 3.2.8 *Let Ω be a (G,H)–2–gauge transformation. Then, for any curve $\gamma : p_0 \rightarrow p_1$ of M, one has*

$$G_{{}^{\Omega}g_{|\theta},{}^{\Omega}J_{|\theta};\theta}(\gamma) = \tilde{\Omega}(p_1)^{-1}G_{g,J;\theta}(\gamma)m(F_\theta(\gamma))(\tilde{\Omega}(p_0)) \tag{3.2.14}$$

where $\tilde{\Omega}$ is related to Ω by the relation

$$\tilde{\Omega} = m(g^{-1})(\Omega). \tag{3.2.15}$$

From a categorical point of view, it can be shown that a (G,H)–2–gauge transformation Ω encodes a modification $\bar{G}_{g,J;\theta} \Rrightarrow \bar{G}_{{}^{\tilde{\Omega}}g_{|\theta},{}^{\tilde{\Omega}}J_{|\theta};\theta}$ of gauge pseudonatural transformations of parallel transport functors.

3.3 2–holonomy

In this subsection containing the main results of this paper, we shall illustrate the theory of higher holonomy based on the framework of sect. 2.

We consider first ordinary knot holonomy in a gauge theory with gauge Lie group G on a manifold M.

Let C be a differentiable compact closed curve with a choice of pointing p_C (cf. def. 2.2.3). Recall that with any free C–knot ξ of M (cf. def. 2.2.4) there is associated a curve $\gamma_\xi : \xi(p_c) \rightarrow \xi(p_c)$ via eq. (2.2.10).

Definition 3.3.1 *Let θ be a flat G–connection on M. For any free C–knot ξ of M, the holonomy of ξ is the element $F_\theta(\xi) \in G$ defined by*

$$F_\theta(\xi) = F_\theta(\gamma_\xi). \tag{3.3.1}$$

The datum required by the construction of knot holonomies is thus a flat G–connection θ on M (cf. def. 3.1.1, eq. (3.1.1)), which we fix once and for all.

The construction of the curve γ_ξ of a free C–knot ξ according to (2.2.10) involves a choice of a compatible curve $\gamma_C : p_C \to p_C$ of C (cf. def. 2.2.12). The value $F_\theta(\xi)$ of the holonomy of ξ is however independent from the choice made.

Proposition 3.3.1 *Knot holonomy is independent from the choice of the compatible curve γ_C.*

Proof. By virtue of prop. 2.2.1, the curve γ_ξ of a free C–knot ξ does not depend on the choice of γ_C up to thin homotopy. Since the map $\gamma \mapsto F_\theta(\gamma)$ is thin homotopy invariant for a G–connection θ (cf. prop. 3.1.2), $F_\theta(\gamma_\xi)$ does not depend on the choice of γ_C. The statement follows now readily from (3.3.1). ☐

In order the definition of knot holonomy that we have given to be topologically meaningful, the holonomies of ambient isotopic free C–knots (cf. def. (2.2.5)) should be equivalent in a suitable sense. As it turns out, they are equivalent modulo G–conjugation.

To study this matter, we first assign a C–pointing p_M to M (cf. def. 2.2.6) and consider C–knots of M (cf. def. 2.2.10, eq. (2.2.8)). Recall that C–knot ambient isotopy is C–pointing preserving (cf. def. 2.2.11).

Proposition 3.3.2 *If ξ_0, ξ_1 are C–knots of M and ξ_0, ξ_1 are ambient isotopic,*

$$F_\theta(\xi_1) = F_\theta(\xi_0). \tag{3.3.2}$$

Proof. By prop. 2.2.2, under the stated hypotheses, there is a homotopy $\gamma_{\xi_0} \Rightarrow$

γ_{ξ_1}. Since the map $\gamma \mapsto F_\theta(\gamma)$ is homotopy invariant for a flat G–connection θ (cf. prop. 3.1.2), $F_\theta(\gamma_{\xi_0}) = F_\theta(\gamma_{\xi_1})$. By (3.3.1), (3.3.2) then holds. $\square$

Suppose now that two distinct C–pointings p_{M0}, p_{M1} of M are given. The holonomies of two C–knot ξ_0, ξ_1 of respectively M_0 and M_1 which are freely ambient isotopic (cf. def. 2.2.14), though not strictly equal, are related by a simple G–conjugation.

Proposition 3.3.3 *If ξ_0, ξ_1 are C–knots of M_0 and M_1, respectively, and ξ_0, ξ_1 are freely ambient isotopic, then*

$$F_\theta(\xi_1) = F_\theta(\gamma_1)F_\theta(\xi_0)F_\theta(\gamma_1)^{-1}, \tag{3.3.3}$$

where $\gamma_1 : p_{M0} \to p_{M1}$ is a curve of M.

Proof. By prop. 2.2.3, under the stated hypotheses, there exist a curve $\gamma_1 : p_{M0} \to p_{M1}$ of M and a homotopy $\gamma_{\xi_0} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{\xi_1} \circ \gamma_1$. Again, as the map $\gamma \mapsto F_\theta(\gamma)$ is homotopy invariant for a flat G–connection θ (cf. prop. 3.1.2), $F_\theta(\gamma_{\xi_0}) = F_\theta({\gamma_1}^{-1\circ} \circ \gamma_{\xi_1} \circ \gamma_1) = F_\theta(\gamma_1)^{-1}F_\theta(\gamma_{\xi_1})F_\theta(\gamma_1)$, where (3.1.5), (3.1.6) have been used. By (3.3.1), (3.3.3) then holds. $\square$

Next, we allow the pointing of C to be changed. Suppose that two pointings p_{C0}, p_{C1} of C are given and that M is C–pointed by p_{M0}, p_{M1}. We denote by $F_{\theta 0}$, $F_{\theta 1}$ the holonomy maps associated with the two pointings of C, that is $F_{\theta 0}(\xi) = F_\theta(\gamma_{0\xi})$, $F_{\theta 1}(\xi) = F_\theta(\gamma_{1\xi})$ with ξ a free C_0– and C_1–knot, respectively, in accordance with (3.3.1) (cf. subsect. 2.2).

Proposition 3.3.4 *If ξ is both a C_0–knot of M_0 and a C_1–knot of M_1, then*

$$F_{\theta 1}(\xi) = F_\theta(\gamma_1)F_{\theta 0}(\xi)F_\theta(\gamma_1)^{-1}, \tag{3.3.4}$$

where $\gamma_1 : p_{M0} \to p_{M1}$ is a curve of M with image lying in that of ξ.

Proof. By prop. 2.2.4, under the hypotheses, there are a curve $\gamma_1 : p_{M0} \to p_{M1}$

of $M$and a thin homotopy $\gamma_{0\xi} \Rrightarrow \gamma_1{}^{-1\circ} \circ \gamma_{1\xi} \circ \gamma_1$, both with image contained in that of ξ. Again, since the map $\gamma \mapsto F_\theta(\gamma)$ is homotopy invariant for a flat G–connection θ, $F_\theta(\gamma_{0\xi}) = F_\theta(\gamma_1)^{-1} F_\theta(\gamma_{\xi_1}) F_\theta(\gamma_1)$, by a calculation similar to that done to prove (3.3.3). By (3.3.1), (3.3.4) then follows readily. □

Knot holonomy $\xi \mapsto F_\theta(\xi)$ depends on the flat G–connection θ used in a gauge covariant manner (cf. def. 3.2.2, eq. (3.2.1)). Let again M be C–pointed by p_M.

Proposition 3.3.5 *Let ξ be a C–knot of M. Then, for any G–gauge transformation g, then one has*

$$F_{{}^g\theta}(\xi) = g(p_M) F_\theta(\xi) g(p_M)^{-1}. \tag{3.3.5}$$

Proof. If p is a point and $\gamma : p \rightarrow p$ is a closed curve based at p, then one has $F_{{}^g\theta}(\gamma) = g(p) F_\theta(\gamma) g(p)^{-1}$, by (3.2.2). Then, on account of (3.3.1) and the fact that $\gamma_\xi : p_M \rightarrow p_M$, we have $F_{{}^g\theta}(\gamma_\xi) = g(p_M) F_\theta(\gamma_\xi) g(p_M)^{-1}$. (3.3.5) follows immediately from this relation and (3.3.1). □

We consider next surface knot holonomy in a strict higher gauge theory with gauge Lie crossed module (G, H) on a manifold M. Let S be a compact closed differentiable surface with a choice of marking (cf. def. 2.2.20). Recall that with any S–surface knot $\varXi$ and its $2\ell_S$ characteristic C–knots $\zeta_{Si}{}^*\varXi$ (cf. defs. 2.2.21, 2.2.23), there are associated the normalized surface $\varSigma^\sharp{}_\varXi : \iota_{p_M} \Rrightarrow \iota_{p_M}$ and the curves $\gamma_{\zeta_{Si}{}^*\varXi} : p_M \rightarrow p_M$ via eqs. (2.2.35), (2.2.37) and (2.2.39). Recall also that the definition of $\varSigma^\sharp{}_\varXi$ involves the fixing of a concomitant reference S–surface knot $\varXi_{M\varXi}$ (cf. def. 2.2.40).

Definition 3.3.2 *Let $(\theta, \varUpsilon)$ be a flat (G, H)–2–connection doublet on M. For any free S–surface knot $\varXi$ of M, the 2–holonomy of $\varXi$ is the element $F_{\theta,\varUpsilon}(\varXi)$ $\in H$ defined by*

$$F_{\theta,\varUpsilon}(\varXi) = F_{\theta,\varUpsilon}(\varSigma^\sharp{}_\varXi) \tag{3.3.6}$$

and the 1*–holonomies of the characteristic* C*–knots* $\zeta_{Si}{}^*\varXi$ *of* $\varXi$ *are the* $2\ell_S$ *elements* $F_\theta(\zeta_{Si}{}^*\varXi) \in G$ *defined by*

$$F_\theta(\zeta_{Si}{}^*\varXi) = F_\theta(\gamma_{\zeta_{Si}{}^*\varXi}). \tag{3.3.7}$$

We note that, by (2.2.37) and (3.1.14), (3.1.15),

$$F_{\theta,\varUpsilon}(\varXi) = F_{\theta,\varUpsilon}(\varSigma_{M\varXi})^{-1}F_{\theta,\varUpsilon}(\varSigma_{\varXi}), \tag{3.3.8}$$

where $\varSigma_{M\varXi} = \varSigma_{\varXi_{M\varXi}}$. The datum required by the construction of the above knot holonomies is thus a flat (G,H)–2–connection doublet $(\theta,\varUpsilon)$ on M (cf. def. 3.1.3, eq. (3.1.9)), which we fix once and for all.

Proposition 3.3.6 *For any* S*–surface knot* $\varXi$ *of* M*, we have*

$$t(F_{\theta,\varUpsilon}(\varXi)) = 1_H. \tag{3.3.9}$$

Non trivial 2–holonomy is thus possible only if the kernel of t is non trivial.

Proof. If p is a point, $\gamma : p \to p$ is a closed curve based at p and and $\varSigma : \gamma \Rightarrow \gamma$ is a closed surface based at γ, then, by (3.1.12), $F_\theta(\gamma) = t(F_{\theta,\varUpsilon}(\varSigma))F_\theta(\gamma)$. It follows that $t(F_{\theta,\varUpsilon}(\varSigma)) = 1_H$. By (3.3.6), applying this result to the closed surface $\varSigma^\sharp{}_\varXi : \iota_{p_M} \Rightarrow \iota_{p_M}$, we find $t(F_{\theta,\varUpsilon}(\varSigma^\sharp{}_\varXi)) = 1_H$. (3.3.9) follows now immediately from (3.3.6). □

The construction of the normalized surface surface $\varSigma^\sharp{}_\varXi$ of a free S–surface knot $\varXi$ according to (2.2.35), (2.2.37) and the curves $\gamma_{\zeta_{Si}{}^*\varXi}$ according to (2.2.39) involves a choice of a compatible curve γ_C of C and a compatible surface $\varSigma_S : \iota_{p_S} \Rightarrow \tau_S$ of S (cf. def. 2.2.31) congruent with it (cf. def. 2.2.32). The values $F_{\theta,\varUpsilon}(\varXi)$ and $F_\theta(\zeta_{Si}{}^*\varXi)$ of the 2–holonomy of $\varXi$ and the 1–holonomies of the $\zeta_{Si}{}^*\varXi$ are however independent from the choices made.

Proposition 3.3.7 *Surface knot holonomy is independent from the choice of the compatible curve* γ_C *and surface* $\varSigma_S$ *congruent with it.*

Proof. By virtue of prop. 2.2.6, the normalized surface ${\mathit{\Sigma}^\sharp}_{\mathit{\Xi}}$ of a free S–surface knot $\mathit{\Xi}$ does not depend on the congruent choice of γ_C and $\mathit{\Sigma}_S$ up to thin homotopy. Since the map $\mathit{\Sigma} \mapsto F_{\theta,\mathit{\Upsilon}}(\mathit{\Sigma})$ is thin homotopy invariant for a (G,H)–2–connection doublet $(\theta,\mathit{\Upsilon})$ (cf. prop. 3.1.5), $F_{\theta,\mathit{\Upsilon}}({\mathit{\Sigma}^\sharp}_{\mathit{\Xi}})$ does not depend on the congruent choice of γ_C and $\mathit{\Sigma}_S$. Reasoning as in the proof of prop. 3.3.1, one finds that $F_\theta(\gamma_{\zeta_{Si}{}^*\mathit{\Xi}})$ does not depend on the choice of γ_C The statement follows now readily from (3.3.6) and (3.3.7). $\square$

As for ordinary knots, in order the definition of surface knot holonomy that we have given to be topologically meaningful, the 2–holonomies of ambient isotopic free S–surface knots (cf. def. (2.2.22)) as well as the 1–holonomies of their attached characteristic C–knots should be equivalent in a suitable sense. Further, the 2–holonomy of a given S–surface knot corresponding to ambient isotopic choices of the concomitant reference S–surface knots (cf. def. 2.2.40) should also be equivalent in the same sense. As we are going to show below, all these holonomies are equivalent modulo the appropriate form of (G,H)–crossed module conjugation.

To study this matter, we first assign a S–marking $\{p_M,\zeta_{Mi}\}$ to M (cf. def. 2.2.24) and restrict ourselves to S–surface knots of M (cf. def. 2.2.28, eqs. (2.2.26)). Recall that S–surface knot ambient isotopy is S–marking preserving (cf. def. 2.2.30).

Suppose that we are given two choices $\mathit{\Xi}_{M0}$, $\mathit{\Xi}_{M1}$ of the reference S–surface knot. For any S–surface knot $\mathit{\Xi}$, we let $F_{\theta,\mathit{\Upsilon}}(\mathit{\Xi}_{|0}) = F_{\theta,\mathit{\Upsilon}}({\mathit{\Sigma}^\sharp}_{\mathit{\Xi}|0})$, $F_{\theta,\mathit{\Upsilon}}(\mathit{\Xi}_{|1}) = F_{\theta,\mathit{\Upsilon}}({\mathit{\Sigma}^\sharp}_{\mathit{\Xi}|1})$ be the corresponding 2–holonomies of $\mathit{\Xi}$ constructed according to (3.3.6) (cf. subsect. 2.2).

Proposition 3.3.8 *If the reference S–surface knots $\mathit{\Xi}_{M0}$, $\mathit{\Xi}_{M1}$ are ambient isotopic, then for any S–surface knot $\mathit{\Xi}$*

$$F_{\theta,\mathit{\Upsilon}}(\mathit{\Xi}_{|1}) = F_{\theta,\mathit{\Upsilon}}(\mathit{\Xi}_{|0}). \tag{3.3.10}$$

Proof. Under the above hypothesis, for every S–surface knot $\varXi$ there is a homotopy ${H_M}^\sharp : {\varSigma^\sharp}_{\varXi|0} \Rrightarrow {\varSigma^\sharp}_{\varXi|1}$ (cf. prop. 2.2.7). Since the map $\varSigma \rightarrow F_{\theta,\varUpsilon}(\varSigma)$ is homotopy invariant for a flat (G, H)–2–connection doublet $(\theta, \varUpsilon)$ (cf. prop. 3.1.5), $F_{\theta,\varUpsilon}({\varSigma^\sharp}_{\varXi|0}) = F_{\theta,\varUpsilon}({\varSigma^\sharp}_{\varXi|1})$. From (3.3.6), the statement then follows. □

Proposition 3.3.9 *If $\varXi_0$, $\varXi_1$ are S–surface knots of M and $\varXi_0$, $\varXi_1$ are ambient isotopic, then one has*

$$F_{\theta,\varUpsilon}(\varXi_1) = F_{\theta,\varUpsilon}(\varXi_0) \tag{3.3.11}$$

and likewise

$$F_\theta({\zeta_{Si}}^*\varXi_1) = F_\theta({\zeta_{Si}}^*\varXi_0). \tag{3.3.12}$$

Proof. By prop. 2.2.8, under the stated hypotheses, there is a homotopy ${\varSigma^\sharp}_{\varXi_0} \Rrightarrow {\varSigma^\sharp}_{\varXi_1}$. Again, as the map $\varSigma \rightarrow F_{\theta,\varUpsilon}(\varSigma)$ is homotopy invariant for a flat (G, H)–2–connection doublet $(\theta, \varUpsilon)$ (cf. prop. 3.1.5), $F_{\theta,\varUpsilon}({\varSigma^\sharp}_{\varXi_0}) = F_{\theta,\varUpsilon}({\varSigma^\sharp}_{\varXi_1})$. From (3.3.6), (3.3.11) follows.

By prop. 2.2.10, under the same hypotheses, $\gamma_{{\zeta_{Si}}^*\varXi_1} = \gamma_{{\zeta_{Si}}^*\varXi_0}$, so that $F_\theta(\gamma_{{\zeta_{Si}}^*\varXi_1}) = F_\theta(\gamma_{{\zeta_{Si}}^*\varXi_0})$. From (3.3.7), (3.3.12) also follows. □

Suppose now that two distinct S–markings $\{p_{M0}, \zeta_{M0i}\}$, $\{p_{M1}, \zeta_{M1i}\}$ of M are given. The 2 holonomies of two S–surface knots $\varXi_0$, $\varXi_1$ of respectively M_0 and M_1 which are freely ambient isotopic (cf. def. 2.2.14) as well as the 1–holonomies of their attached characteristic C–knots ${\zeta_{Si}}^*\varXi_0$, ${\zeta_{Si}}^*\varXi_1$, though different in general, are related by a form of (G, H)–conjugation. We remind the reader the notion of concordance introduced in def. 2.2.39.

Proposition 3.3.10 *Assume that the reference S–surface knots $\varXi_{M0}$, $\varXi_{M1}$ of M_0. M_1, respectively, are freely ambient isotopic. If $\varXi_0$, $\varXi_1$ are S–surface knots of M_0. M_1, respectively, and $\varXi_0$, $\varXi_1$ are freely ambient isotopic through an isotopy concordant with that of $\varXi_{M0}$, $\varXi_{M1}$ on $\{p_{M0}, \zeta_{M0i}\}$, then there are a curve γ_1 :*

$p_{M0} \to p_{M1}$ and $2\ell_S$ surfaces $\Sigma_i : \gamma_{\zeta_{Si}{}^*\Xi_0} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1$, of M such that

$$F_{\theta,\Upsilon}(\Xi_1) = m(F_\theta(\gamma_1))(F_{\theta,\Upsilon}(\Xi_0)) \tag{3.3.13}$$

and similarly that

$$F_\theta({\zeta_{Si}}^*\Xi_1) = F_\theta(\gamma_1)t(F_{\theta,\Upsilon}(\Sigma_i))F_\theta({\zeta_{Si}}^*\Xi_0)F_\theta(\gamma_1)^{-1}. \tag{3.3.14}$$

Proof. According to prop. 2.2.11, under the above hypotheses, there exists a curve $\gamma_1 : p_{M0} \to p_{M1}$ and a homotopy $\Sigma^\sharp{}_{\Xi_0} \Rrightarrow {I_{\gamma_1}}^{-1\circ} \circ \Sigma^\sharp{}_{\Xi_1} \circ I_{\gamma_1}$. Again, by the homotopy invariance of the map $\Sigma \to F_{\theta,\Upsilon}(\Sigma)$ for a flat (G,H)–2–connection doublet (θ,Υ) (cf. prop. 3.1.5), we have

$$\begin{aligned}F_{\theta,\Upsilon}(\Sigma^\sharp{}_{\Xi_0}) &= F_{\theta,\Upsilon}({I_{\gamma_1}}^{-1\circ} \circ \Sigma^\sharp{}_{\Xi_1} \circ I_{\gamma_1})\\ &= m(F_\theta(\gamma_1)^{-1})\big(F_{\theta,\Upsilon}(I_{\gamma_1})^{-1}F_{\theta,\Upsilon}(\Sigma^\sharp{}_{\Xi_1})m(F_\theta(\iota_{p_{M1}}))(F_{\theta,\Upsilon}(I_{\gamma_1}))\big)\\ &= m(F_\theta(\gamma_1)^{-1})(F_{\theta,\Upsilon}(\Sigma^\sharp{}_{\Xi_1})),\end{aligned}$$

where (3.1.4), (3.1.5), (3.1.13), (3.1.16), (3.1.17) have been used. By (3.3.6), this relation is equivalent to (3.3.13).

According to prop. 2.2.12, under the same hypotheses, for each i there exists a homotopy $\gamma_{\zeta_{Si}{}^*\Xi_0} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1$, which we presently view as a surface Σ_i with the same source and target curves, γ_1 being the same curve as the one featured above. Again, by the homotopy invariance of the map $\gamma \to F_\theta(\gamma)$ for a flat (G,H)–2–connection doublet (θ,Υ) (cf. prop. 3.1.5), we have

$$\begin{aligned}t(F_{\theta,\Upsilon}(\Sigma_i))F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_0}) &= F_\theta({\gamma_1}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1)\\ &= F_\theta(\gamma_1)^{-1}F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_1})F_\theta(\gamma_1),\end{aligned}$$

where (3.1.5), (3.1.6) have been used. Using (3.3.7), this relation immediately reduces to (3.3.14). □

Next, we allow the marking of S to be changed. Suppose that two markings

$\{p_{S0},\zeta_{S0i}\}$, $\{p_{S1},\zeta_{S1i}\}$ of S with the same underlying C–pointing p_C are given and that M is S–marked by $\{p_{M0},\zeta_{M0i}\}$, $\{p_{M1},\zeta_{M1i}\}$. We denote by $F_{\theta,\Upsilon 0}$, $F_{\theta,\Upsilon 1}$ and $F_{\theta 0}$, $F_{\theta 1}$ the 2– and 1–holonomy maps associated with the two markings of S, that is $F_{\theta,\Upsilon 0}(\varXi) = F_\theta({\varSigma^\sharp}_{0\varXi})$, $F_{\theta,\Upsilon 1}(\varXi) = F_\theta({\varSigma^\sharp}_{1\varXi})$ and $F_{\theta 0}({\zeta_{S0i}}^*\varXi) = F_\theta(\gamma_{0{\zeta_{S0i}}^*\varXi})$, $F_{\theta 1}({\zeta_{S1i}}^*\varXi) = F_\theta(\gamma_{1{\zeta_{S1i}}^*\varXi})$ with $\varXi$ a free S_0– and S_1–surface knot, respectively, in accordance with (3.3.6), (3.3.7) (cf. subsect. 2.2).

Proposition 3.3.11 *Suppose that the reference S_0–surface knot $\varXi_{M0}$ of M_0 and S_1–surface knot $\varXi_{M1}$ of M_1 are both equal to a simultaneous S_0– and S_1 surface knot $\varXi_M$ of M_0 and M_1 perhaps up to S_0– and S_1–marking preserving ambient isotopy, respectively. Let $\varXi$ be a simultaneous S_0– and S_1–surface knot of M_0 and M_1, respectively, having the following properties: $\varXi\circ k_z(p_{S0}) = \varXi_M\circ k_z(p_{S0})$ and $\varXi\circ k_z\circ\zeta_{S0i} = \varXi_M\circ k_z\circ\zeta_{S0i}$ for all z, where k_z is an orientation preserving isotopy with the properties stated in lemma 2.2.1. Then, there are a curve $\gamma_1 : p_{M0}\to p_{M1}$ and $2\ell_S$ surfaces $\varSigma_i : \gamma_{0{\zeta_{S0i}}^*\varXi} \Rightarrow {\gamma_1}^{-1\circ}\circ\gamma_{1{\zeta_{S1i}}^*\varXi_1}\circ\gamma_1$, of M all with image lying in that of $\varXi$ such that*

$$F_{\theta,\Upsilon 1}(\varXi) = m(F_\theta(\gamma_1))(F_{\theta,\Upsilon 0}(\varXi)) \tag{3.3.15}$$

and similarly that

$$F_{\theta 1}({\zeta_{S1i}}^*\varXi) = F_\theta(\gamma_1)t(F_{\theta,\Upsilon}(\varSigma_i))F_{\theta 0}({\zeta_{S0i}}^*\varXi)F_\theta(\gamma_1)^{-1}. \tag{3.3.16}$$

Proof. By prop. 2.2.13, under the above hypotheses, there exist a curve $\gamma_1 : p_{M0}\to p_{M1}$ and a thin homotopy ${\varSigma^\sharp}_{0\varXi} \Rrightarrow {I_{\gamma_1}}^{-1\circ}\circ{\varSigma^\sharp}_{1\varXi}\circ I_{\gamma_1}$, both with image contained in that of $\varXi$. Using once more the homotopy invariance of the map $\varSigma\to F_{\theta,\Upsilon}(\varSigma)$ for a flat (G,H)–2–connection doublet (θ,Υ) (cf. prop. 3.1.5), by a calculation similar to that carried out to prove (3.3.13), we find that $F_{\theta,\Upsilon}({\varSigma^\sharp}_{0\varXi}) = m(F_\theta(\gamma_1)^{-1})(F_{\theta,\Upsilon}({\varSigma^\sharp}_{1\varXi}))$. By (3.3.6), this relation is equivalent to (3.3.15).

According to prop. 2.2.14, under the same hypotheses, there exist $2\ell_S$ homotopies $\gamma_{0\zeta_{S0i}{}^*\Xi} \Rightarrow {\gamma_1}^{-1\circ} \circ \gamma_{1\zeta_{S1i}{}^*\Xi_1} \circ \gamma_1$ with image contained in that of Ξ, which we now view as surfaces Σ_i with the same source and target curves, γ_1 being the same curve as the one described above. Exploiting again the homotopy invariance of the map $\gamma \to F_\theta(\gamma)$ for a flat (G,H)–2–connection doublet (θ,Υ) (cf. prop. 3.1.5), by a calculation similar to that worked out to show (3.3.14), we find that $t(F_{\theta,\Upsilon}(\Sigma_i))F_\theta(\gamma_{0\zeta_{S0i}{}^*\Xi}) = F_\theta(\gamma_1)^{-1}F_\theta(\gamma_{1\zeta_{S1i}{}^*\Xi_1})F_\theta(\gamma_1)$. Using (3.3.7), this relation immediately reduces to (3.3.16). ☐

As in the case of ordinary knots, surface knot holonomy $\xi \mapsto F_\theta(\xi)$ depends on the flat (G,H)–2–connection doublet (θ,Υ) used in a gauge covariant manner (cf. def. 3.2.4, eqs. (3.2.3)). Let again M be S–marked by $\{p_M, \zeta_{Mi}\}$.

Proposition 3.3.12 *Let Ξ be an S–surface knot of M. Then, for any (G,H)–1–gauge transformation (g,J), one has*

$$F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Xi) = m(g(p_M))(F_{\theta,\Upsilon}(\Xi)) \tag{3.3.17}$$

and correspondingly that

$$F_{{}^{g,J}\theta}({\zeta_{Si}}^*\Xi) = g(p_M)t(G_{g,J;\theta}({\zeta_{Si}}^*\Xi))F_\theta({\zeta_{Si}}^*\Xi)g(p_M)^{-1}, \tag{3.3.18}$$

where the gauge 1–holonomies $G_{g,J;\theta}({\zeta_{Si}}^*\Xi))$ are given by

$$G_{g,J;\theta}({\zeta_{Si}}^*\Xi) = G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi}). \tag{3.3.19}$$

Proof. If p is a point, $\gamma : p \to p$ is a closed curve based at p and $\Sigma : \gamma \Rightarrow \gamma$ is a closed surface based at γ, then $F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma) = m\big(g(p)t(G_{g,J;\theta}(\gamma))\big)(F_{\theta,\Upsilon}(\Sigma))$, by (3.2.7). Then, by virtue the fact that $\iota_{p_M} : p_M \to p_M$ and $\Sigma^\sharp{}_\Xi : \iota_{p_M} \Rightarrow \iota_{p_M}$, we obtain that $F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma^\sharp{}_\Xi) = m\big(g(p_M)t(G_{g,J;\theta}(\iota_{p_M}))\big)(F_{\theta,\Upsilon}(\Sigma^\sharp{}_\Xi))$. Using the property that $G_{g,J;\theta}(\iota_{p_M}) = 1_H$ following immediately from def. 3.2.5, eqs. (3.2.4), (3.2.5), and the fact that $\mathrm{rank}(d\iota_{p_M}(x)) = 0$, we find so $F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma^\sharp{}_\Xi) = m(g(p_M))(F_{\theta,\Upsilon}(\Sigma^\sharp{}_\Xi))$. Recalling (3.3.6), we reach (3.3.17).

If p is a point and $\gamma : p \to p$ is a closed curve based at p, then $F_{{}^{g,J}\theta}(\gamma) = g(p)t(G_{g,J;\theta}(\gamma))F_\theta(\gamma)g(p)^{-1}$, by (3.2.6). Then, by (3.3.7) and the fact that $\gamma_{\zeta_{Si}{}^*\Xi} : p_M \to p_M$, we have $F_{{}^{g,J}\theta}(\gamma_{\zeta_{Si}{}^*\Xi}) = g(p_M)t(G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi}))F_\theta(\gamma_{\zeta_{Si}{}^*\Xi})g(p_M)^{-1}$. Recalling (3.3.7) and using the notation (3.3.19), we reach (3.3.18). $\square$

The gauge 1–holonomies of the characteristic C–knots of two freely ambient isotopic S–surface knots are related in a computable way.

Proposition 3.3.13 *Under the same hypotheses and with the same specifications of prop. 3.3.10, the gauge* 1*–holonomies* $G_{g,J;\theta}(\zeta_{Si}{}^*\Xi_0)$, $G_{g,J;\theta}(\zeta_{Si}{}^*\Xi_1)$ *are related as follows,*

$$\begin{aligned} G_{g,J;\theta}(\zeta_{Si}{}^*\Xi_1) = G_{g,J;\theta}(\gamma_1)m(F_\theta(\gamma_1))\big(&m(g(p_{M0})^{-1})(F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma_i)) \\ &\times G_{g,J;\theta}(\zeta_{Si}{}^*\Xi_0)m\big(F_\theta(\zeta_{Si}{}^*\Xi_0)F_\theta(\gamma_1)^{-1}\big)(G_{g,J;\theta}(\gamma_1)^{-1})F_{\theta,\Upsilon}(\Sigma_i)^{-1}\big). \end{aligned} \tag{3.3.20}$$

Proof. As shown in the proof of prop. 3.3.10 based on prop. 2.2.12, for each i there exists a surface $\Sigma_i : \gamma_{\zeta_{Si}{}^*\Xi_0} \Rightarrow \gamma_1{}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1$. Using (3.2.7), we have

$$\begin{aligned} &G_{g,J;\theta}(\gamma_1{}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1) \\ &\quad = m(g(p_{M0})^{-1})(F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma_i))G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi_0})F_{\theta,\Upsilon}(\Sigma_i)^{-1}. \end{aligned} \tag{3.3.21}$$

From (3.1.5) and (3.2.9), (3.2.10), we find

$$\begin{aligned} &G_{g,J;\theta}(\gamma_1{}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*\Xi_1} \circ \gamma_1) \\ &\quad = m(F_\theta(\gamma_1)^{-1})\big(G_{g,J;\theta}(\gamma_1)^{-1}G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi_1})m(F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_1}))(G_{g,J;\theta}(\gamma_1))\big). \end{aligned} \tag{3.3.22}$$

Inserting (3.3.22) into (3.3.21), we get

$$\begin{aligned} G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi_1}) = G_{g,J;\theta}(\gamma_1)m(F_\theta(\gamma_1))\big(&m(g(p_{M0})^{-1})(F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma_i)) \\ &\times G_{g,J;\theta}(\gamma_{\zeta_{Si}{}^*\Xi_0})F_{\theta,\Upsilon}(\Sigma_i)^{-1}\big)m(F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_1}))(G_{g,J;\theta}(\gamma_1)^{-1}). \end{aligned} \tag{3.3.23}$$

The last factor in the right hand side of (3.3.23) can be reshaped using the calculation of the proof of prop. 3.3.10,

$$m(F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_1}))(G_{g,J;\theta}(\gamma_1)^{-1}) \tag{3.3.24}$$

$$
\begin{aligned}
&= m\big(F_\theta(\gamma_1)t(F_{\theta,\Upsilon}(\Sigma_i))F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_0})F_\theta(\gamma_1)^{-1}\big)(G_{g,J;\theta}(\gamma_1)^{-1})\\
&= m(F_\theta(\gamma_1))\big(F_{\theta,\Upsilon}(\Sigma_i)m\big(F_\theta(\gamma_{\zeta_{Si}{}^*\Xi_0})F_\theta(\gamma_1)^{-1}\big)(G_{g,J;\theta}(\gamma_1)^{-1})F_{\theta,\Upsilon}(\Sigma_i)^{-1}\big).
\end{aligned}
$$

Substituting (3.3.24) into (3.3.23) and using (3.3.7) and (3.3.19), we reach immediately (3.3.20). □

The gauge 1–holonomies of the characteristic C–knots of an S–surface knot with respect two marking of S are also related in a computable way Below, we denote by $G_{g,J;\theta 0}$, $G_{g,J;\theta 1}$ the gauge 1–holonomy maps associated with the two markings, that is $G_{g,J;\theta 0}(\zeta_{S0i}{}^*\Xi) = G_{g,J;\theta}(\gamma_{0\zeta_{S0i}{}^*\Xi})$, $G_{g,J;\theta 1}(\zeta_{S1i}{}^*\Xi) = G_{g,J;\theta}(\gamma_{1\zeta_{S1i}{}^*\Xi})$ with Ξ a free S_0– and S_1–surface knot, respectively, in accordance with (3.3.19).

Proposition 3.3.14 *Under the same hypotheses and with the same specifications of prop. 3.3.11, the gauge 1–holonomies $G_{g,J;\theta 1}(\zeta_{S0i}{}^*\Xi)$, $G_{g,J;\theta 1}(\zeta_{S1i}{}^*\Xi)$ are related as*

$$
\begin{aligned}
G_{g,J;\theta 1}(\zeta_{S1i}{}^*\Xi) &= G_{g,J;\theta}(\gamma_1)m(F_\theta(\gamma_1))\big(m(g(p_{M0})^{-1})(F_{{}^{g,J}\theta,{}^{g,J}\Upsilon}(\Sigma_i)) \\
&\quad\times G_{g,J;\theta 0}(\zeta_{S0i}{}^*\Xi)m\big(F_{\theta 0}(\zeta_{S0i}{}^*\Xi)F_\theta(\gamma_1)^{-1}\big)(G_{g,J;\theta}(\gamma_1)^{-1})F_{\theta,\Upsilon}(\Sigma_i)^{-1}\big).
\end{aligned}
\tag{3.3.25}
$$

Proof. The proof proceeds by a reasoning and calculations essentially identical to those of prop. 3.3.13. □

We now analyse the effect of source autodiffeomorphism action on holonomy.

We consider first an ordinary gauge theory with gauge Lie group G on a manifold M with a flat G–connection θ.

Proposition 3.3.15 *Let ξ be a free C–knot and let f be an orientation preserving autodiffeomorphisms of C. Then,*

$$
F_\theta(f^*\xi) = F_\theta(\gamma_f)F_\theta(\xi)F_\theta(\gamma_f)^{-1}, \tag{3.3.26}
$$

where $\gamma_f : \xi(p_C) \to f^*\xi(p_C)$ is a curve of M whose image lies in that of ξ.

Proof. By prop. 2.3.3, under the above hypotheses, there are a curve $\gamma_f : \xi(p_C) \to f^*\xi(p_C)$ and a thin homotopy $\gamma_\xi \Rightarrow {\gamma_f}^{-1\circ} \circ \gamma_{f^*\xi} \circ \gamma_f$, both with image contained in that of ξ. The statement then follows from a reasoning analogous to that of the proof of prop. 3.3.3. □

We consider next a strict higher gauge theory with gauge Lie crossed module (G, H) on a manifold M with a flat (G, H)–2–connection doublet (θ, Υ).

Proposition 3.3.16 *Let $\varXi$ be a free S–surface knot and let f_0, f_1 be isotopic orientation preserving autodiffeomorphisms of S. Suppose that the concomitant reference S–surface knots $\varXi_{M{f_0}^*\varXi}$, $\varXi_{M{f_1}^*\varXi}$ of ${f_0}^*\varXi$, ${f_1}^*\varXi$ are ${f_0}^*\varXi_{M\varXi}$, ${f_1}^*\varXi_{M\varXi}$, respectively, where $\varXi_{M\varXi}$ is the concomitant reference S–surface knot of $\varXi$. Suppose further that the free ambient isotopies relating ${f_0}^*\varXi$, ${f_1}^*\varXi$ and ${f_0}^*\varXi_{M\varXi}$, ${f_1}^*\varXi_{M\varXi}$ according to prop. 2.3.5 are concordant on the S–marking $\{{f_0}^*\varXi(p_S), {\zeta_{Si}}^*{f_0}^*\varXi\}$ of M. Then, there are a curve $\gamma_{f_0f_1} : {f_0}^*\varXi(p_S) \to {f_1}^*\varXi(p_S)$ of M and $2\ell_S$ surfaces $\varSigma_{f_0f_1i} : \gamma_{{\zeta_{Si}}^*{f_0}^*\varXi} \Rightarrow {\gamma_{f_0f_1}}^{-1\circ} \circ \gamma_{{\zeta_{Si}}^*{f_1}^*\varXi} \circ \gamma_{f_0f_1}$, all with image is contained in that of $\varXi$ such that*

$$F_{\theta,\Upsilon}({f_1}^*\varXi) = m(F_\theta(\gamma_{f_0f_1}))(F_{\theta,\Upsilon}({f_0}^*\varXi)) \tag{3.3.27}$$

and similarly that

$$F_\theta({\zeta_{Si}}^*{f_1}^*\varXi) = F_\theta(\gamma_{f_0f_1})t(F_{\theta,\Upsilon}(\varSigma_{f_0f_1i}))F_\theta({\zeta_{Si}}^*{f_0}^*\varXi)F_\theta(\gamma_{f_0f_1})^{-1}. \tag{3.3.28}$$

Proof. By prop. 2.3.6, under the above hypotheses, there are a curve $\gamma_{f_0f_1} : {f_0}^*\varXi(p_S) \to {f_1}^*\varXi(p_S)$ of M and a thin homotopy ${\varSigma^\sharp}_{{f_0}^*\varXi} \Rrightarrow {I_{\gamma_{f_0f_1}}}^{-1\circ} \circ {\varSigma^\sharp}_{{f_1}^*\varXi} \circ I_{\gamma_{f_0f_1}}$, both with image lying in that of $\varXi$. Using once more the homotopy invariance of the map $\varSigma \to F_{\theta,\Upsilon}(\varSigma)$ for a flat (G, H)–2–connection doublet (θ, Υ) (cf. prop. 3.1.5), by a calculation similar to that carried out to prove (3.3.13), we find that $F_{\theta,\Upsilon}({\varSigma^\sharp}_{{f_0}^*\varXi}) = m(F_\theta(\gamma_{f_0f_1})^{-1})(F_{\theta,\Upsilon}({\varSigma^\sharp}_{{f_1}^*\varXi}))$. By (3.3.6), this relation is equivalent to (3.3.27).

According to prop. 2.3.7, under the same hypotheses, there exist $2\ell_S$ homotopies $\gamma_{\zeta_{Si}{}^*f_0{}^*\varXi} \Rightarrow \gamma_{f_0f_1}{}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*f_1{}^*\varXi} \circ \gamma_{f_0f_1}$ with image contained in that of $\varXi$, which we now view as surfaces $\varSigma_{f_0f_1i}$ with the same source and target curves, $\gamma_{f_0f_1}$ being the same curve as the one described above. Exploiting again the homotopy invariance of the map $\gamma \to F_\theta(\gamma)$ for a flat (G,H)–2–connection doublet $(\theta,\varUpsilon)$ (cf. prop. 3.1.5), by a calculation similar to that worked out to show (3.3.14), we find that $t(F_{\theta,\varUpsilon}(\varSigma_{f_0f_1i}))F_\theta(\gamma_{\zeta_{Si}{}^*f_0{}^*\varXi}) = F_\theta(\gamma_{f_0f_1})^{-1}F_\theta(\gamma_{\zeta_{Si}{}^*f_1{}^*\varXi})F_\theta(\gamma_{f_0f_1})$. Using (3.3.7), this relation immediately reduces to (3.3.28). □

Proposition 3.3.17 *Under the same hypotheses of prop. 3.3.16, one has*

$$\begin{aligned} G_{g,J;\theta}(\zeta_{Si}{}^*f_1{}^*\varXi) = G_{g,J;\theta}(\gamma_{f_0f_1})m(F_\theta(\gamma_{f_0f_1}))\big(\\ m(g(f_0{}^*\varXi(p_S))^{-1})(F_{{}^{g,J}\theta,{}^{g,J}\varUpsilon}(\varSigma_{f_0f_1i}))G_{g,J;\theta}(\zeta_{Si}{}^*f_0{}^*\varXi) \\ \times\, m\big(F_\theta(\zeta_{Si}{}^*f_0{}^*\varXi)F_\theta(\gamma_{f_0f_1})^{-1}\big)(G_{g,J;\theta}(\gamma_{f_0f_1})^{-1})F_{\theta,\varUpsilon}(\varSigma_{f_0f_1i})^{-1}\big). \end{aligned} \tag{3.3.29}$$

Proof. This follows from a calculation analogous to that leading (3.3.20) using the homotopies $\gamma_{\zeta_{Si}{}^*f_0{}^*\varXi} \Rightarrow \gamma_{f_0f_1}{}^{-1\circ} \circ \gamma_{\zeta_{Si}{}^*f_1{}^*\varXi} \circ \gamma_{f_0f_1}$ discussed in the proof of (3.3.28) above. □
